1. Re: divide by 10 at 150 mhz

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-01 02:01:14 UTC
From: k7itm@aol.com
Message-ID: <3200347.0212311801.6be321be@posting.google.com>
Source record: 38904

Four ideas: as mentioned elsewhere, use a CPLD; use 74AC/ACT devices
(some go to that sort of freq); use a PLL chip such as one of the
National PLLatinum series, some of which can be programmed to simply
act as a divider; use one of the ideas from www.wenzel.com:
http://www.wenzel.com/pdffiles/dividers.pdf has some interesting
thoughts for simple ways to divide freqs, esp. if the input varies
over a limited range.

Cheers,
Tom

Uh, didn't germanium diode have marking like that? And used in SWP/Watt meters?

Date: 2003-01-01 02:59:30 UTC
From: Ross <rjtucke@asu.edu>
Message-ID: <rjtucke-9EA12B.20015731122002@news.west.cox.net>
Source record: 38905

OK! I think I've finally implemented what everybody was telling me. Except, infuriatingly, I've been having a ridiculous challenge over a SIMPLE THREE-LEG circuit. What I need is the very general differential equations for the following circuit:

```
C
C-----||-----|
L C  |
C f(t)|
C*-/\/\/--0--*
C R  _|_
_|_  ///
///
```

where the C is a capacitor, the L is an inductor with the tap at 1 turn (of N total turns) above ground, the R is a resistor, and f(t) above the 0 represents a CURRENT source.

This is just a simple three leg circuit, yet because it's a current source and because the inductor will act as an autotransformer, I keep fearing that I'm messing it up...

So yes, I'm actually being blatently impertinant in that I am asking for the DEs rather than simply how to do it. I deeply appreciate your time.
Ross

Well, you have a good start for a Hartley oscillator, but the current
source in series with a resistance gives the tank infinite Q. This gets
messy.

You could put the resistor in parallel with the current source, or change
the current source to a voltage source.

The impedance reflected across the tank is Rp = R * N. The resonant
frequency for usable Q's is the standard F = 1 / (2 * pi * sqrt(LC))

Then, XL = 2 * pi * F * L

and

Q = (R * N) / XL

In other words, for reasonable operating Q, R needs to be high if it is
in series with a voltage source, or low if it is in parallel with a

current source.

Another way, if you are headed towards making an oscillator, is to set XL = XC = 50 to 200 ohms, then continue from there. You'd like the Q to be as high as possible, but practical coils may range from 50 or so to over 400.

For a Hartley using a FET, tapping the coil 25% from the bottom is a good starting point. If you use bipolar, the tap should be 25% from the top.

The bipolar has a slight disadvantage since the bias circuit will be in parallel with the tank and will reduce the Q. The FET can have a bypassed source resistor and the tank can be grounded, which can result in higher Q.

Mike

5. Re: Almost done with that regen question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-01 08:11:27 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <v158lfjgrrteff@corp.supernews.com>
Source record: 38908

If the current is assumed positive to the left, and I2 is the current through C, positive to the right, the Laplace transformed loop equations are:

```
V + IR - (I*Ls)*(1-N)/N^2 + I2*Ls*(1-1/N) + I2/Cs = 0
V + IR - (I*Ls)*(1-N)/N^2 + (I-I2)*Ls/N = 0
```

where I(s) is the Laplace transform of current f(t), V is the voltage across the current source, with the positive terminal to the right, and I2 is the current through the capacitor, positive to the right. These can be solved for the two unknowns V and I2.

If you're able to work directly with the differential equations, I'm sure it'll be no problem for you to perform the inverse transforms to get them.

It could be an OA90 (white=9, black=0), which is a germanium diode made
by Philips or some other European manufacturer.

Germanium diodes are used in SWR meters because of their low turn-on
(threshold) voltage, which helps to give more accurate readings near the
bottom of the scale - for example when reading 'reflected power' with a
good impedance match. You don't say in what way the 1N914 "doesn't
work", but it is a silicon diode with a higher threshold voltage, which
will make the meter more reluctant to start moving up from zero.

I don't know if the OA90 is still manufactured, but a typical US-made
germanium detector diode such as the 1N82A should work OK.

SINAD'ers (@ 1KHz tone) are available for a very low price at the hamfests so it may be better to buy one unless your intent is to build for educational value. Also, if you know someone with a SINAD meter, go there and measure 12 db several times and after a while your ear will be able to tell you when you're within a db or so of 12 db. I haven't done a 12 db SINAD measurement in about 20 years or so, but I would be willing to bet some money on my ear to set to within 1 db easily. Of course, your application may determine that you need absolute readings for doing off channel measurements, for instance. This is a horse of a different colour.

Hi all!

I would think this is a 1N90 (white 9, black 0).
Aquick search says: germanium-diode.
Mayby anyone with a databook at hand can verify this and
post the data.

All the best to you in 2003

Hi. I hardly know anything about SPICE (or electronics for that matter), but I've been tring to find stuff on the web about tube RF circuit simulation using SPICE. Not found much. Anyone know of any sites on the subject? I've seen audio tube models, but not much data for RF pentodes.

I'd like to simulate a local oscillator that uses a CV327 (EF52), and the mixer that uses a CV302 (ECH22). I won't hold my breath. :c) TIA. Rich.

While this isn't exactly in a can, the ink in Sharpie markers acts as a
positive resist.

Actually I'm not designing, but mainly just want to know the local osc.
output. Probably simpler to just build up the circuit, get some test
gear and measure the output. But, would be an interesting
diversion/project to use SPICE.

Tony

Giving people additional data often helps. Things like "it's in a wattmeter" obviously made a lot of folks think through other alternatives. Wattmeters frequently use germanium diodes, which are fairly unusual in other services, and if you replaced a germanium diode with a 1N914 you would probably get incorrect readings, especially at lower power levels. The other connection someone made is that the color code matched "90" and discovered a 1N90 is a germanium diode. Again, without knowing it was in a wattmeter you wouldn't expect a germanium diode.

But there is some other data here, too. You said the unit was struck by lightning. Are you sure it's (only) the diode? Is the meter receiving the current it should? Perhaps the meter movement itself was munged up and the diode isn't the problem.

It's always worth validating what you think you know!

And you still haven't described what you mean by "not working right". Again, more specific behavior is likely to tickle the memory of someone reading this thread.

..

Source record: 38918

Well in theory that all sounded pretty good, BUT I went ahead and replaced the 1N914 with a 1N90 and it didn't make any difference. Meter deflects backwards when powered up and in the forward power reading mode. It shows deflection when a transmitter is keyed but the readings are way off. Any other ideas? It's a Diamond SX-1000 (the same one I'm trying to get a schematic on).

I suggested it might be an OA90 (because I have some OA91s that are colour-coded in that way). I never mentioned a 1N90 - never even heard of it.

> Meter deflects
>backwards when powered up and in the forward power reading mode.

In that case the diode is connected the wrong way round.

There have been a number of kits on and off but mostly they seem to be very expensive or they disappear about the time I'm ready to buy one <g>

Sheldon Hands has several, though, and if you don't have to translate Sterling to dollars and then ship them across the pond they may not be quite as expensive to you as they are to me.

Question for the group while we are on the subject.
Is there a practical frequency limit using garden variety diodes like
1N914 and 1N4148 for such a circuit? I recently had to replace a failed
diode in my MFJ-941D and I simply used a non-descript one off of an old
boombox circuit board and it seems fine.
Of course this is hardly a lab instrument but I've always wondered just
how high in freq one should be able to rely on reasonable results?

Tnx,
Bill WX4A

22. If you are looking for a splendid simple project for 2003!...I've got one.

Hello all,

A very Happy New Year to you and yours.

Well, let me begin...

Every once in a blue moon I post a message explaining of my amazing one transistor FM receiver with just a 12 component count in the receiver itself!

Without compromizing for...

...sensitivity
...selectivity
...and audio output

...this little jem is doing its' job just fine!

I call it 'The Radio Shack Special', since all of the parts may be purchased their. In fact, that is why I call it by that name. No need to have to mail order and WAIT for your component(s) to come in.

When you get to the website, just scroll down until you see the words...

THE RADIO SHACK SPECIAL PROJECT

Also, under that will be stories by Pedro, Philip and Murphy about their maiden voyage of the Radio Shack Special. Do read that also...it will surely give you MORE of an incentive to find out what you are getting into.

Should this peak your interest, I am here, my friend, to help in any way that I can to make the journey come out well.

The site is at: http://braincambre500.freeservers.com

...and let the project begin!

Respectfully,

Patrick Cambre

P.S. I thank each and every one of you who took the time out to read my letter. Again, thank you.

Yes, such a diodes construction can't handle frequencies over 2.6GHz in a
practical manner all though you may get them to work.

There is plenty of DOS left in Windows, just make a boot disk!

It might just be germanium, or a Schottky. Just be sure that the one
you try is okay at your operating frequency.

27. Quaker Oats Antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-02 02:49:51 UTC
From: James Hilins <jhilins@wi.rr.com.REMOVE>
Message-ID: <jNNQ9.67765$Zt4.793271@twister.rdc-kc.rr.com>
Source record: 38930

(Receive only antenna for Antique Console Radios)

I'm going to turn a loop antenna on Quaker oats tube. The Idea here is to turn enough to get it resonant some where in the AM radio band, then tap off shorter for higher freq SW bands. I have a bag of 1.5pf - 5pf variable capacitors to help tune the impedance.

So I hope to pick the brain trust out there to help save some time and experimentation.

One idea is to turn it from the center of the tube to one end clock wise and from the center to the other end counter clockwise center tap it and use the trim cap to cancel out the inductance. This way the currents are opposite but equal (kind of like a dipole wrapped on a oatmeal box, with each leg wound in opposite directions) I'll keep adding turns until my MFJ antenna analyzer is happy.

Another idea is to turn it from one end to the other attach ground to one end and then start tapping from the other end for AM and SW bands use the trim capacitors as needed to cancel inductance.

Anyone out there have any experience with this? Any other construction techniques?

Jim Hilins

That sounds interesting, but...
If you wind the two legs in opposite directions, the two loaded-dipole coils could generate voltages out of phase with each other - possibly cancelling at the feedpoint.
You can use a single-turn loop with a large amount of capacitance, or a multiple-turn loop with less capacitance, or even a loop wound on a ferrite core as most portable AM radios use. However you make it, a loop will be a highly directional antenna, with a narrow bandwidth.
I'd guess your second idea will be more successful.
However, the antique radios I've seen already have well-designed loop antennas mounted inside. They were usually made to be used with a random wire antenna, to be attached to a fahnstock clip or screw terminal somewhere on the back of the radio. The longer the wire, and the better the ground connection, the better those old receivers worked.

hi James:

for BCB you may consider building a box loop. these are big antennas [some make them using a hula hoop] requiring a large value variable capacitor. antenna directionality is key to good BCB reception. loops allow you to pull in a station of interest while nulling out interfering ones as well as local noise. a space saving option would be to build a larger ferrite loop. regen is also an option. look at this link...

Ctrl-P to get Plotting and Printing dialogue, then Windows button to check
you have the correct printer selected, then Run button. This should output
the schematic to your printer, properly scaled to A4.

Email me if you still have problems.

Ext. battery pack for Yaesu vx5r

I want to build a battery pack for my vx5r, but need to clarify something
before go ahead.

Q1. will ext battery damage the vx5r if I connect the battery pack for
several hours and with 50% time of signal transmission ?
Q2. what is best voltage supply(e.g. 6/12v from lead-acid type or
7.2/9.6v from series of 1.2v cell) to vx5r ?
Q3. which type is the better, lead-acid or NiCd/NiMh cell ?

Happy New Year!

Discovered that one of my HP182C scopes has vertical amplifier 1801A
and it is marked 50MHz, while the other has type 1808A and it is
marked 75MHz.

Wonder if somebody knows what the difference is and whether the old
unit may be modified for 75MHz ? I have access to the manuals*, but
believe it is for the 1801A type only.

Also have 8558A (w/manual). Believe it was a modification to be done
for use with the spectrum analyser, some of the controls on the upper
right does seem to function properly as they are today.

>You have a very good memory. I haven't touched one of those since about
>1967!

Just estimation. Experimented with different rigs to achieve good CW
keying where the tube were not biassed too much out of the active
region and using a voltage divider such that 6146B's har higher
negative bias at KEY-UP than 12BY7 and 6AU6.
FT-902 keys only 12BY7A and 2x6146B, I modified the rig in '88, and
have got ufb reports on the keying. Also modified with fb reports
TR-7010, FT-221R, IC-202, FT-101B. Modified the HX-20, but it was soon
wrecked, on the other hand it was an interesting experiment which
added to the experience, so no problem, it is just part of fun with
the hobby.

It is not important whether the anode current is 10 or 20µA, it won't
probably not oscillate even when current is 0.5mA. So it really depend
on the coupling in the oscillator. Perhaps you need only a few volts
KEY-UP-voltage.

73 es happy new year!

I have to jump in here & explain Analog Devices sample policy.
We deliberately make up to 2 samples available of many of our ICs.
Do not consider using this facility as dishonest.
I was involved (along with some other AD employees who happen to also
be radio amateurs) in discussing how to set up this facility in the
1st place.
1 reason for my involvement was down to the UK (RSGB) magazine
publishing a number of homebrew articles that used our parts.
The admin costs of sending samples by any other means , or indeed of
getting payment & processing orders for 1 or 2 parts, outweigh the
cost to ADI of the free sample service we now provide.
It is deliberately intended as much for amateurs , hi-fi experimenters
and hobbyists as it is for real customers with a commercial production
project in mind.
We sold the process to our "bean counters" by pointing out the
excellent PR that should spin off from this - quite a few professional
engineers are also hobbyists and quite a few young hobbyists evolve to
become pro-engineers.

Chris

Thank you very much for that clarification. As someone else who works in a large company, I understand how expensive it can be to process a small order, and knowing that amateurs were part of the intent of that sample process certainly helps.

And in response to Mike, I get the impression that the parts are available in production qualities, it's just that the hobbyist distributor network is a little weak. The parts certainly show up in lots of things.

Not as such. There is a complex matrix of priorities to try to satisfy the needs of individuals, small companies & "blue chip" ones (or "Tier 1" customers if you prefer).
It is a deliberate policy to try to make **some** samples available even when products are in short supply ; sometimes the shortage is caused by a Tier 1 customer who happens to have a poor forecasting/planning system also.
If samples aren't available, we lose out in the all important "design-in" period irrespective of whether the sample request is for a key customer or a smaller one ; we will not always recognise the large-potential ones anyway as so many large companies now either contract out some of their designs or employ contract workers for some or all of the design process.
Added to this , most semiconductor companies' attempts to answer questions relating to promised delivery times (against orders or requests) are likely to be woefully inaccurate. I have lost count of the number of times I have checked out on behalf of a worried customer why they have been quoted (for example) 4 months to get a couple of ICs when we have several thousand sitting in a warehouse somewhere in the world - and I know the same happens with our competitors too.
This boils down to a mixture of poor/late data entry , incompatible software logistics and/or production systems, inefficient data query systems and similar nightmares. I assume other industries have comparable problems but I only know about ours ICs).

Please don't cry too much for me though - I enjoy the technical side and try not to get involved in commercial or logistics issues (but we do get dragged into them at times).

Apologies for taking the original (laudable) thread OT
This lot should really be under its own separate heading.

While they aren't rated, one clue is the switching speed in
on-off time specs...the shorter those are, the higher the
frequency. Semiconductor folks tend to get rather arty on
"majority and minority carrier storage" terms to define an
upper frequency limit. Not much help there.

While disassembling a floppy disk drive motor I came across 3 devices inside the motor case on the motor coil pcb. They have 4 legs and are very small, plastic encapsulated beasties but no ID marking. I think they might be Hall Effect Sensors, but I can only find 3 leg HE sensors described on the web.

Anyone know what they are.. and how to use 'em ?

Many Thanks, Happy New Year etc..

Chris, I thank you for convincing management to provide free samples.
This has often helped decide which chip to use.

But is there any truth to the observation that samples are easier to get
than production quantities? I have heard the same comment before in other
newsgroups.

If they're black and shiny on one face with a bevelled edge opposite the edge with the leads, they are IR detectors. If that matches your discription, I'm pretty sure I can give you the pinout.

Yes, I've heard horror stories of sudden product cancellations without prior notice. People also complain about dealing with Linear Technology.

Motorola dumped their entire RF line last year, and cut the notice time in half. MaCom supposedly picked up the line, but who knows what problems a new vendor will encounter? Fortunately, Philips carries some equivalents, such as the PBR941 to replace the MMBR941.

Just wait till the economy picks up again. Many of the good parts will go on allocation, and everyone will be screaming about not being able to make their ship deadlines.

Yes, I agree that Maxim are making very nice chips (at least on paper)
that could be used in many amateur radio projects. However, I have
often wondered, how on earth are they able to produce so many new
chips every month as indicated by their monthly newsletters. At least
I have the impression that the company is much smaller than the giants
like Intel, TI or Motorola with huge R&D departments.

If I understood a recent Maxim newsletter correctly, they are able to
produce multiple chips on a single wafer, which would be nice for
producing a small number of samples, but this would also explain why
it is so hard to get any production volumes.

Unfortunately I have the feeling that they and some other chip
manufacturers are actually waiting for some firm orders before
starting the actual production of a specific chip.

Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.swap,rec.radio.swap

Hello there,

I've got a programming adapter - cable for the Kenwood TK880 & TK780 radios to sell. I use the kpg49d software and have at... bought this one from an online dealer less than a six months ago for over $100 by the time the postage/shipping smoke cleared. But when your in the field and in a hurry, you have to get the job done asap.

This adapter might also work on similar series models, i.e. the 800 & 900 Mhz units, of which I have none myself. This unit is in great (near new) condition, not a home-brew perf board prototype unit often seen on Ebay.

So this near new programming adapter/cable unit is for sale for $55 and a few bucks postage.
Figure $60 will get it to your door USPS with delivery confirmation.

Please take the NOSPAMPLEASE out of my Email address below, after you've cut and pasted it into your Email program to contact me. If you reply direct to this post, notice the whacky header above to reduce spam.

Thanks and I'll be happy to answer any related questions you have. I have an all positive 625 plus Ebay feedback rating, same as my Email address if you need easy references.

cheers

Popular parts are sometimes very hard to get. Distributors often
take advantage of this and jack the pricing.

However, if you often need small to medium quantities (<100 pieces) you
should sign up for buy-online. You get a good ship date and book price
on the parts.

I use a lot of AD parts, and have only had a couple of problems over the
years.

There appear to be a number of facets to the availability problem.
Factory MOQ is an easily understood concept, but many down-line
distributors nowadays are afraid to warehouse most chips from outfits
like Maxim and LT - they simply don't want to tie up cash in "flavour
of the month" chips which could be dead stock inside 12 months.

Unfortunately, factory MOQ's are set from one point of view only, and
I suspect that there is a (mistaken?) belief at the fab house that
distributors do in fact warehouse and therefore offer MOQ's lower than
fcatory MOQ. [All bets are off when SMD or other tape/reel-mount
components are under discussion.]

Using my own example for Maxim, the local dist here in Western
Australia is Arrow. Because of this lack of warehousing, all orders
go back up the food chain through Arrow Australia to Arrow US and back
to Maxim. They schedule a production batch when there is enough
ordered quantity to justify a run.

Sometimes, this system defeats the best intentions of the chip maker,
and sample quantities may not suffice. We had occasion to produce a
proto batch of 20 Li-Ion chargers using the MAX1737. Factory (and
therefore Arrow) MOQ was too high. Sample quantities were too low.
We eventually located an offshore distributor who HAD actually
warehoused the chip, and we were able to purchase in 50 quantities
off-the-shelf.

Who is responsible for the poor availability? I believe the factory
rationale is reasonable, with a view to economy of production and
supply. I also believe that the down-line distributors need to
warehouse and break FMOQ quantities down so that chips will move.
Apart from places like Farnell and RadioSpares, there aren't many
warehousers out there breaking FMOQ's. Even with a price for singles
at five times the reel quantity, Farnell do provide a much needed
service to startups.

<snip>

> Wonder if somebody knows what the difference is and whether the old
> unit may be modified for 75MHz ?

While it may be possible, in some way, to expand the bandwidth on
the 50MHz unit, it is unlikely that doing so will be easy, cheap, or even
worth the effort given the age of the equipment, parts availability, etc.
In fact, if you look at the date codes on the parts for the two plug-ins,
you will probably see that they differ by some number of years.

In short; HP probably used very different designs for both the
plug-ins. I know Tektronix certainly did for theirs. You'd probably be
better off just looking for another 75MHz plug-in at whatever ham swap or
electronic surplus place(s) are close to you, or perhaps on Ebay.

Good hunting.

Source record: 38874

Hi Mike.

I can't tell from the picture you posted but I'm pretty sure that it is a Hall Effect sensor.

The three terminal Hall sensors have built in amplifiers and Schmitt trigger, plus a voltage regulator and output stage.
The four terminal type are just the Hall element alone. Called 'Naked Hall Effect" sensors by some.
The motor is most likely a three phase DC brushless type and there will be a brushless controller chip that receives the signals from these sensors and drives the motor phases. The amplifiers, voltage regulator and Schmitt trigger will be built into the controller chip.
If you trace the wiring, you should see (assuming these are 'Naked" Hall Effect sensors) two of the pins of each wired in series. That wasn't very clear: Imagine Xmas tree lights in series. Anyway, the current flows through one set of pins and a differential signal is generated across the other two.

Oh, and why the sensors? To detect the position of the rotor of the motor to properly time the commutation of the windings.

I had run into that scenerio when I was working at my last employer. I had ordered some reels of new products from Maxim, only to be told two months later that they had a bad run. When they offerred me an alternate new part that still had to be put throught its initial test, I decided to go along with Analog Devices instead.

Greenweld, Mainline and Display Electronics cannot help.

Maybe someone here has something or can recommend other surplus sources for a SMPS PCB with universal AC input and 13.8v DC out at 2A. Either a fixed output voltage or a 15v psu with voltage adjust pot.

I require several hundred of these, at least.

How much do I wish to pay?

Answer, not a lot.

Pound, euro's or dollars talk.

I don't mind importing if the price is right.

intended only for binary file dumps, and your message will likely get
either lost in the noise or outright cancelled.

Now, with that said...

> The info I found indicated that the Orcad Capture software was
> availabe free on a CD offered by Orcad. It's supposed to be a top
> shelf pcb design and schematic editing software package for Windows.

Frankly, I think the older DOS version did a better job. Anyway,
yes, OrCAD is considered, at least by OrCAD marketdroids, to be a 'top-
shelf' package.

However, only the 'Demo' (30-day time limit) version is free. The
unlocked version costs many thousands of $$.

You may be better off with Eagle, CircuitMaker/TraxMaker,
Electronics Workbench, or other less-expensive packages. OrCAD is aimed
at the professional engineering and commercial manufacturing markets, and
is most definitely priced accordingly. I know of very few hams who use it
on a personal basis.

Try some of these links.

http://www.cadsoft.de/ (for Eagle)

http://www.electronicsworkbench.com/

http://www.microcode.com/ (for CircuitMaker/TraxMaker)

The only caution I would add, in reference to Microcode's products,
is that they were bought out by Protel/Altium several years ago. Protel
pulled this stunt because they, apparently, couldn't write a SPICE
simulator to save their bacon. Rather than do it right on their own, they
pulled a Billy-Boy Gates by buying out someone else who already had.

It is my belief that the CircuitMaker/TraxMaker product pair has
suffered significantly, in terms of both support and future development,
as a result of this unholy partnership. This is because Protel (now
Altium) markets a high-end EDA package of their own.

If they let the lower-end packages get too good, people will start favoring them over the more expensive stuff. I did not see any significant advantage to "upgrading" from my older CircuitMaker/TraxMaker ver. 6/PRO product to the current '2000' series. In fact, based on the bug reports and complaints I learned about later for the 2000 series, this turned out to be a very wise decision.

Things may have improved by now. I don't know. I've not had any contact with the company for some time. I do know that user complaints and bug reports, both for the older and newer product (and even, in some cases, for the high-end Protel 99SE package) used to be met with lukewarm marketing-type responses at best, or stony silence at worst. The latter was certainly the case with some of the reports I made.

Good luck.

I would say to eliminate the unknowns, as you can. What I mean is, find someone with a kenwood hand mic for that rig.. try it, and see if the audio is still "harsh" also if this is on the higher bands, 12 m and up, you may need a better ground, you may be getting rf into your audio section... make sure you have a good earth ground to the back...

Source record: 38878

Hi,

Even with a simulation coming up with the output level of a typical sine wave oscillator is pretty tough.

Most approaches wind up being

1) I know this current (or voltage) is = X
2) I simulate the circuit
3) I adjust the simulation so the current (or voltage) is right
4) I read off the output when the simulation is running that way

The problem is that if you don't already know the magic current or voltage level you are stuck. Knowing the magic level pretty much implies that you have the circuit running in front of you.

Take Care!

Hi,

This data is from the last time I did one of these - something like 40 years ago so it may be a little off :)

Your best bet is to space wind the wire on the tube. If you use number 24 to 28 gauge wire put about three or four wire diameters between each turn. Fill half to 2/3 of the tube with turns. The idea is more turns = more signal.

As you wind it scotch tape may be helpful to keep it all in place.

Once the winding is done varnish it in place. Almost any urethane varnish will do just fine.

To get into the radio wrap a few turns of insulated wire on top of the main winding. Make sure the turns are all in the same direction.

You can resonate the coil over the entire BC band and it will work fairly well. Getting up to short wave will be a problem. The losses in the coil will more or less eat you alive.

You will probably need a couple hundred pf to get it to resonate on the low end of the band.

One helpful resource for some of this is http://www.btinternet.com/~g4fgq.regp/ . Reg has a lot of cute little programs to quickly calculate things like what the net inductance will be.

Take Care!

Hi,

I know that I have heard that expression in the distant past but cannot for the life of me remember what it means. However, a web search brings up the fact that a certain Madam Sorenson was wed at the bottom of the stairs in the Peery Hotel, Salt Lake City. From which I gather she was well known at the time (1920's ??). Perhaps she was a latter-day Lizzie Borden and chopped everything up or maybe she had here own set of trimming tools and a wobbulator and went round touching thing up :-(

Hi Everyone,

I've used turbo cad some, but my version is very old (ver 3). The old version does not do electronic schematic drawing.

I've been looking for some software that would simple schematic editing and printing/saving to files.

I called the turbocad people and the lady I spoke to was very very nice. She didn't know a transistor from an IC however and really couldn't answer my questions about the abilities of turbocad to draw schematics. Perhaps I should have asked to talk to another rep who had knowledge of schematic drawing capability and features, but I didn't.

I know that there is some support for turbocad on the website, but I really need to chat with a turbocad user that does electronics and schematic drawing/editing in turbocad.

Some simple questions.....

1-Is the software specifically made to draw schematics (self layout and self completing lines if you tell it you want a connection between pin 4 of U1 and pin 9 of U2)? Or, do I have to determine where I want the particular line to run on the drawing and multiple click (basically drawing the line myself)?

2-Is it really schematic drawing friendly or is it a mechanical drawing program with a few electronic symbols on the cd rom?

3-Is there any real and practical reason for me to buy the latest version (ver 8.2)? I see some version 7's on ebay, new in the box for around 10 to 15 dollars...but they don't have hard copy book type manuals with them.

Before answering question 3, consider that I rarely dabble in circuits with more than 3 chips and 5 transistors and I want to print them and archive them to digital files and be able to make revisions and edit the diagrams. I don't need spice, pcb layout/design or any of that really pricey stuff that comes with Orcad.

Send me a sign please.

And, thanks alot!

Art

As I recall, my version came with libraries of electrical and
electronic components. If yours didn't, you could make your own
blocks or symbols.

>1-Is the software specifically made to draw schematics (self layout

I'm not aware of any program that will automagically make connections
on a schematic. I use Protel (a fairly expensive electronic CAD
system) and I do have to draw the schematic myself.

>2-Is it really schematic drawing friendly or is it a mechanical
>drawing program with a few electronic symbols on the cd rom?

TurboCad is primarily a mechanical drawing program - but should be OK
for simple schematics (I've used AutoCad for some fairly complex
wiring diagrams.)

Keep in mind that "drawing" programs *will not* create schematics that
can be netlisted, thus their value is very limited.

Print it into a ps file. That's what I do in Tango schematic (dos program also
and pretty good for what I need it).

I have Orcad-SDT here...it'd take some effort to assemble up and zip.

I can burn a CD...runs under DOS, and is VERY fast and easy to use.

Only downside is that the printer drivers are very very old...

The "free" demo CD versions of Orcad offer a little more flexibility but
you cannot save the files. I still prefer the DOS version. It can be
easily configured to run under windows.

Even Windows2000? My old DOS tools (Protel Autotrax and Orcad) won't
run under Windos2000.

Message-ID: <OmpR9.237358$a8.233456@news4.srv.hcvlny.cv.net>
Source record: 38893

Hi,

Well the post office fooled me this time. The letter arrived today. It's dated December 30th. The "official" frequencies turned out to be:

3579335.2 Hz
7046882.3 Hz
14049083.8 Hz
21069674.5 Hz

I blew the 80 meter measurement. Now I have to figure out why. All of them came in under a hertz but 80 meters was off by 180 ppb. The rest came in at 30 to 40 ppb.

Enjoy!

I have used the AD9854 in a DDS design as a hobbyist - I was able to get small quantities (5) through a standard distributor
At AUS$60 this is not cheap but still small beer for a commercial company. I think this is reasonable given that there is a small hobbyist market for these complex SM devices.

I got the "S2001A" from the manual. I didn't get to see the actual tubes yet, (they are behind some shielding and I didn't bother to remove that since everything works fine right now). You are probably right, it must be some Kenwood number.

Thanks for the help everybody!

Hi Jan,

No, you're thinking of a UPS.

Commonly called a Useless Power Supply, which of course it is not,
especially in an emergency.

If you have a standard SWR bridge you should be able to pull of something
that you could scale properly for the tuner.

If you don't, I think the ARRL Handbook has directions on building SWR
bridges.

Good Day all,

What happens to old cell phones? They seem to be throw away devices, even tho they still work after the contract runs out. These days 2 years of use makes the phone ancient and worthless, regardless of whether it still works or not.

But these things are full of good rf parts sensitive 800 mhz receivers that can be put on 900 mhz ham bands and 3 watt transmitters that can run cw or fm---since the receiver and the transmitter have to run in close proximity to each other (and in full duplex), their LO's and transmitter spectral output has to be squeaky clean. Of course, there is a duplexer and the thing is loaded with top quality UHF rf components. Some of them have 'test modes' which allows the user to tune and transmit and manually control the frequencies from the keypad.

Anyway, I never see service manuals or other technical information for these things and a one year old cellphone goes for 20 bucks or less on ebay these days! 2 year old cell phones go for 3 for 20 bucks or so..

Has anyone hacked into these and published any information on using them for alternative purposes???? Or gaining control of these things in service mode? Does anyone deal in Service Manuals for these things??

Email me or post reply here.

Have a great day.

Our church collects them for an outfit that programs them so that
they only call 911 or *55, and then donates them to battered womens'
shelters for distribution. This is A Good Thing.

The VX5 (and anything with Li batteries) has a smart charger. You
won't overcharge the cell. Transmitting 50% of the time will heat up
the radio, though. Probably best to use the lowest power setting
that will do the job.

>Q2. what is best voltage supply(e.g. 6/12v from lead-acid type or

>Q3. which type is the better, lead-acid or NiCd/NiMh cell ?

Take your pick based on cost and availability. Do you already
have a charger for one or the other?

It may be there's not much market for the manuals, as the repairs will
likely cost near or more than what the phone's worth.

Not very exciting, but you can salvage a pager motor out of
most of them. They also have a very accurate temperature-compensated
oscillator.

But they are also a source of other interesting radio parts. IF filters, usually at exotically high frequencies (and crystals that convert those IFs to 455KHz, complete FM IF strips for that matter, frequency prescalers, diode double balanced mixers, synthesizer ICs of various kinds, sometimes interesting RF transistors, and sundry other parts. For that matter, I have more than enough NE570 companders because I've stripped cellphones. Except that they are often oddly shaped, cellphones supply nice metal cases.

Of course, I'm referring to older and bulkier phones, when the components were nice and big, and just as important standard and not too integrated. I've bought them for fifty cents to five dollars (I think that's my limit) at garage and rummage sales, and if it's old and bulky and you want RF parts they are worth the money.

I can't say the same thing for more recent ones. Certainly hand held cellphones yield increasingly fewer parts. I got a recent one for fifty cents, and there was virtually nothing that I could recognize inside. Another one at least had a recognizable first IF filter.

Try your local OSRAM distributor- they make a very nice unit, about the size of a cigarette packet, designed for 12v halogen lamps, good for several amps. Also meets European standards for RF crud emission. Cheap, competitive with conventional iron core transformers. (I got some as samples - very nice pieces of engineering...)

If you look through the Usenet archives (http://groups.google.com),
Yo will fine a brief post or two on my efforts, to that date, of kind
of reverse engineering and re-using a bag/transmobile type phone.

The key really, is to use only the RF/IF strip, and essethinally
dump/replace the CPU/Control boards with something you can
control (I was programming the PLLs with a PC)

Hi,

Well there are three answers to the question. Two are simple but not of much use the other is not quite so simple.

The easy one is - it's all based on capacitances and they are in the data sheet. More or less it's grid to cathode capacitance plus grid to plate capacitance times the voltage gain. That's nice but you need quite a bit more to actually design an amplifier. This is just enough information to make you dangerous.

The next level up is - if you run the drive up so that you have grid current then there is a resistive part of the impedance. More or less it comes out to grid current / drive voltage. Still only enough information to get you in a lot of trouble.

Now for the real answer - if you want the amplifier to work none of the above matters a whole lot. Sorry about that.

Here's the problem. You want the amplifier to be stable. Even with a tetrode this is not a simple problem. If you take a simple circuit, say an tapped tuned circuit and drive the grid off a high source impedance the grid will run just fine. However you will not have enough isolation between grid and plate. The reverse transfer capacitance will dump to much of the output back in to the input. The amp will oscillate and possibly detonate :)

The common solution to the problem is to slap a big old non inductive resistor on the grid. Something nice and low like 50 ohms up to maybe a couple of hundred ohms. This acts as the load impedance for the stage driving the amp and it stabilizes the amp by killing both the forward and the reverse gain. The only twist to this is if you are running at a high enough frequency for the input capacitance to matter. If so you resonate it out with a coil.

There isn't a lot of agreement on just how much you need to kill the gain. Some of it depends on just how weird a load you want the amplifier to be stable in to. For example - an open circuit load might result in a *lot* more gain than normal operation into 50 ohms.

The issue above is by no means limited to tube based amplifiers. All power amplifiers suffer from the same issues. The input circuit and in some cases feedback circuit (neutralization on a tube) are generally designed for stability rather than a match to the device. Circuit analysis software is a pretty nice thing for working this stuff out. Without it I would recommend sticking to a known good design rather than rolling your own.

Take Care!

Yes Sir, you are correct. I am sure there are many transistors...not to
mention resistors/capacitors/etc... in the LM386. I should have clarified
myself into saying that the receiver portion itself only has one
transistor.

It is truly a unique little project. Should you decide to make it one
day, I will gladly help out in any way that I can. Just e-mail me directly
at braincambre500@yahoo.com Any concerns or questions about the
unit, I will be there.

Sincerely,

Patrick

Bob:

Ok.. I guess now I'm more confused than I was.

Maybe I should spell out the reason for the question at hand.

I am, indeed, planning on building a homebrew amp.

I've seen a few schematics that use a resistive input to the grid on the tube, but this strikes me as a bit counterproductive, and maybe a little too simple.

So the plan is to build a torroidal broadband torroidal transformer to match the input impedance of the tube with the output impedance of the radio (and coax).

The hope here is I'll be able to remove the input SWR curve to flat, or as close to it as possible. Most of the designs I've seen have a 1.0:1 SWR at 1.8Mhz and close to 1.7:1 at 29.6 Mhz.. I'm thinking it would be nice to have something like 1.3:1 at each end and 1:1 in the middle (which I'd set to the 20M band).

Is this a silly idea? Should I just drop it and use a purely resistive input, or does this idea have any merit?

TIA

-Chris

This is just a guess.

Back a long time ago I worked at the end of a radio production line. To check the tracking of the LO and TRF we used a goose stick! It was a plastic rod with brass on one end and ferrite on the other. If the tracking was ok, bringing one end or the other end of the "goose" stick near RF tuned circuit would reduce the radio output. The radio, with a noise source as input, was "goosed" across the band (as you changed the radio's frequency from one end of the band to the other you alternated bringing the brass and ferrite end of the stick near the RF tuning coil.) If tracking was OK the output fell when either brass or ferrite retunned the TRF circuit. If the output increased the tracking had to be adjusted. The result being that one made the test by "goosing" the radio across the band.

If one wanted to get the most from a "Hammarlund SP-200", or other receiver in 1950 they had to have the TRF stages track each other and track the VFO.

127. Re: Silly Question re: tubes

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-05 21:39:05 UTC
From: Bob Camp <bob@cq.nu>
Message-ID: <ZB1S9.278498$a8.191390@news4.srv.hcvlny.cv.net>
Source record: 38829

Hi,

Starting with a broadband transformer is not a bad idea by it's self. The important step is the resistor across the transformer. The input to the tube looks like a capacitor. With no resistor the SWR will be pretty high (as in >> 10:1).

The thing that degrades the match at 30 MHz is the capacitance of the tube in parallel with the resistor. In order to flatten things out you will need to switch a coil in when you operate up there. If you leave the coil in at the low end the SWR down there will suffer. If you put the coil in series with the resistor the amplifier will be unstable.

If you wanted a purely resistive broadband input there are ways to design a compensating network. It is a bit complex to do without making the amplifier unstable.

Take Care!

Depends on the levels you are trying to measure. For Ham Radio transmitters -- I purchased a telescoping antenna from radio shack and put a BNC on it. -- it picks up fine for my Ham transmitters.

As I recall the HP 5381A was good up to 80 MHz speced but will measure higher.

Bob:

Well, I had planned on putting a resistor between the transformer and
the grid, something on the order of 20 ohms or so.

Maybe I'll just stick with a purely resistive design, but the
temptation to experimentation is just sometimes too strong.

hello all,

is anyone aware or does anyone have, plans for a monoband ssb/cw rig for 10 meters? already looked at ac6v.com. no joy. wanting to build one for a neat antenna i have just for 10.

what i would really like is to use this hw-101 vfo i have and alot of the other parts from the heath junker to build just the 10 meter section of the hw-101. obviously meusing tubes would not be a problem.

has anyone tried this?

Hi,

Well the resistor needs to go from the grid to ground. A resistor in series with the grid may not do the trick. A lot would depend on the design of the stage driving the amplifier.

Take Care!

If you really want to go the DDS route, I can send you design information, including code and board layouts. I probably wouldn't use a straight DDS; a better way would be to use it as a variable reference in a PLL, using the PLL as a tracking filter to clean up the artifacts.

In one of the application notes at www.linear.com they describe a "noise sniffer" which is just a loop of wire at the end of coax.

==========
Could you be somewhat more specific . If Low Pass ,what would be the
required cut-off freq .
Is is for a mono or multi-band transmitter ?

For QRP level of power (up to 5 Watts RF) simple homebrew filters can be
made with small iron dust toroids in the Txx-6 range.

I think so. I think the tuner electronics are basically looking for a
ratio so they can zero out the reflected current. So if you get the
thing in the general ballpark you should be okay.

Art,

after having tried many cad for schematicks and PCB design I recommend
you give Eagle a try (www.cadsoft.de). The user-interface needs some
time to get used to (as most CAD software).
There is a free version with limits the size of the schematics (1 page)
and the size of the PCB board.

Markus

You can use any wire with a BNC connector, or any oscilloscope probe.
Flat frequency response is unimportant, since you will only be looking
at one at a time.

Just be careful not to put too much voltage into the input.

I wonder if someone has developed a DSP/soundcard SINAD meter solution?

Hi Mike!

I am interested in this design also, but none of your files has reached my
news server. Is it possible for you to send them in a mail/several mails
to me? You can use the address I am using writing this.

153. NEED ADVICE: Vacuum tube grid current?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-07 20:50:22 UTC
From: Ross <rjtucke@asu.edu>
Message-ID: <rjtucke-43C82B.13530607012003@news.west.cox.net>

Hi there.
I'm doing this project for school that involves a complete mathematical analysis of this receiver that I built. The detector (it's a regenerative design) uses a grid-leak method on a 6GH8A pentode.
Let me hasten to say that I'm not asking you for all that! I've got it almost done (I hope) except I need a model for the control grid current. It's a function of Vg and Vp, I beleive. And no, I'm not using SPICE- I find the tailoring of all those fitting parameters more confusing than applying Kirchoff ad finitum to the circuit.
Thank you very much for your time.

Sincerely,
Ross

154. Bird 43 Elements Outside Their Range

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-07 21:57:40 UTC
From: Al Lorona <al_lorona@agilent.com>
Message-ID: <3E1B4D53.AC3B63C8@agilent.com>
Source record: 38756

Has anybody ever swept a Bird 43 element outside its rated frequency range to see how quickly it drops off on either side?

I seem to remember casually measuring I think a 25 - 60 MHz element once and seeing that it was no more than 1 or 2 dB down at 3.5 MHz.

I've already checked the source: Bird Electronics does not publish frequency response curves of their elements on their web site.

Thanks,

Al W6LX

It's been a long long time <1957> since my vacuum tube days but let me meander a bit. Grid Leak established the dc operating point for a Class A amplifier. The grid leak resistor has a distributed capacitor, leakage and circuit stray capacitance, to chassis and to the plate circuit. In the tube there are a series of interelectrode capacitors. The Suppressor grid is generally grounded to chassis to minimize electron backscatter and to break up the Cp to Cg. The screen grid is heavily bypassed. Regeneration is achieved by introducing feedback, variable capacitor or adjusting tube gain, from the plate to the grid with a phase angle between 145 and 225 degrees and a feedback factor very close to but less than unity at the operating frequency.

So, I would begin my model by using a dependent voltage source, % of tube output, with a variable gain, setting loop gain, [forward gain of the amplifier times the feedback factor] [ratio of capacitors, plate to grid leakage], to slightly less than 1, and have a phase shift of 180 degrees nominally with a variance of +/- 45 degrees.

Test the model until the circuit just breaks in oscillation then back off on the feedback a percent or two.

Let me know how it works out.

I think you may need to include the "uramp" in a general voltage
controlled current source. The electron only come out the control grid
and never go in. I think the grid current actually follows something like
an exp() curve near the zero bias point.

Treat the pentode control grid as the plate of a diode detector without any loss of precision.

Essentially, the average DC grid current is equal to the peak value of the RF signal voltage divided by the high-value grid leak resistor. The grid current, of course, flows only on the peaks of the grid sinewave form. Grid current has an operating angle given by -

Theta = 2*InverseCosine(Ea / E)

where E is the peak value of the RF input signal and Ea is the DC voltage across the grid resistor. The difference between Ea and E is very small. But for your purposes Theta can be ignored.

The internal diode resistance, when conducting, can be assumed to be a linear resistance of a few hundred ohms. For normal detector operation it is necessary only that the grid leak resistor be very much greater than the internal diode resistance.

The grid (the diode plate) voltage is then amplified by the pentode in the normal manner, with the mean DC component varying according to the audio modulation. The pentode anode must be decoupled for RF otherwise the RF component is fed into the following audio stages. (A junction transistor works in exactly the same way except that the base must be forward biased by a few tenths of a volt.)

****

A complete analysis (but it's not very complicated) can be found in "Communication Engineering", W.L.Everitt, E.E. Ph.D, 1937, McGraw-Hill Book Company Inc.

This is an old book but should be available in many university technical libraries. It is still the best book on mathematical treatment of vacuum tube circuits in radio receivers and transmitters. Go to the chapter on Vacuum Tube Detectors. I thoroughly recommend it.

None of the following programs deal with detectors but you may find some of then useful with your studies.

Hello fellow hams,

I am appealing to you who are broadcast engineers. Does anyone have an FM broadcast transmitter they do not need or want?

A friend of mine is in desperate need of a 5 KW or greater unit. He has no money...so I am asking for a donation. I will pick up and transport it.

Thanks and please email with any info.

Dan

The low power units are quite narrow band...the higher power units (say,
100W) might be useable ...but why risk it...unless you'e looking for only a
relative measurement.

I have a pair of Icon IC-U16 70cm handhelds.Both are programmed with the same frequecies (I know about Func/159357 etc) On one the numbers of the programmed frequencies appear when I press scan and it does a normal scan the other is the problem as it will not scan, if I hold down the up or down arrows it will scan as long as I hold the key down but will not scan by its self. It is not in priority scan mode. Please can anyone tell me how to get the scan to opperate.

Because they are so very expensive. ?100 ~($160).

The high power elements are quite broadband in power measurement. I don't know about directivity. The low power ones are not. As a result, a 500W or a 1kW 50-125 MHz element can be used on 144 MHz with only a small error. At HF, a 43 is probably not the best choice as the sample line technique is less sensitive than the easy to make broadband transformer detector. Cheaper amateur power meters are adequate at HF.

Intriguing message . I wonder what such a unit will be used for ,I mean a
transmitter with such a high power rating.
For a local community radio station I imagine 100 W would be more than
adequate.
Just curious.

I read in sci.electronics.design that Ross <rjtucke@asu.edu> wrote (in
<rjtucke-43C82B.13530607012003@news.west.cox.net>) about 'NEED ADVICE:
Vacuum tube grid current?', on Tue, 7 Jan 2003:
>I'm doing this project for school that involves a complete mathematical
>analysis of this receiver that I built. The detector (it's a
>regenerative design) uses a grid-leak method on a 6GH8A pentode.
>Let me hasten to say that I'm not asking you for all that! I've got it
>almost done (I hope) except I need a model for the control grid current.
>It's a function of Vg and Vp, I beleive. And no, I'm not using SPICE- I
>find the tailoring of all those fitting parameters more confusing than
>applying Kirchoff ad finitum to the circuit.
>Thank you very much for your time.

The source for arcane lore on vacuum tubes is 'Radio(tron)* Designer's
Handbook, F Langford Smith. The 1998 reprinted edition is ISBN 0 7506
3635 1.

* (tron) was included for the original Australian and the US editions.

Chapter 2, section 8 probably has everything you need, and then some.
You may need to dig around to find if the 6GH8A is similar to one of the
older types for which data is given in the examples.

172. RF signal levels: give me a clue!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-08 15:28:45 UTC
From: Paul Burridge <pb@notthisbit.osiris1.co.uk>
Message-ID: <5ggo1vkm8v6jefeckpau7kfde6aej88skq@4ax.com>
Source record: 38776

Hi all,

I've decided I need to cobble up a relative field-strength meter to carry out some experiments with antenna and PA variations. I want to end up with a meter that can comfortably sense say half a Watt ERP at about 10 feet away from the signal source. Problem is, I can only guess at what the induced voltage in the meter's sniffer coil will be at that combination of power and distance, yet I need a ball park figure to be able to commence designing the amplifier stages for the meter. I'm guessing it'll be in the lowish microvolt range, but that *is* just a figure plucked from out of the air (excuse pun).
Therefore, if anyone's got a more accurate estimate of what I should expect, then please post it here!
I know this a bit like asking how long is a piece of string, but nonetheless I invite the panel's view.

THanks,

p.

Dear Frank,

I am asking for a donated transmitter to help a friend of mine who operates a full power fm. He is a good guy that helps a lot of people in the broadcast industry...but who also has too much pride to get out here and ask for help himself when he is in need. HE is broke and his transmitter is beyond repair.

As a fellow ham I am asking those BROADCAST ENGINEERS out here with a heart who have been in a similar jam at least once in their careers to help out.

Thanks,

Dan

Why not design for the low-microvolt range, and include a
variable attenuator between the loop and the front end?

This would give you the best of both worlds, particularly
if the attenuator steps are decades or deciBels.

I have the PSPICE student version, and I am beginning to use the GUI
(instead of the netlist) for the first time.

Does anyone here know how to add models to the PSPICE GUI? I am
trying to add the D1N34A, and I am new to the PSPICE GUI interface.
When I was using the text netlist instead of the GUI, I simply used
the model command in the file.

The suggestions of Everitt's book or Radiotron Designer's
Handbook are good basic stuff for background (the latter is
probably easier to find as a reference...my "Everitt" is a 1932
edition and somewhat rare).

A problem there is that few tube makers published control
grid current curves in the positive bias region. [I have no
reference on any 6GH8] To do a good work-up on analysis,
those can be done by yourself using a low-duty-cycle
pulsed test rig that is relatively easy to build using an
ordinary "555" timer or equivalent capable of producing the
peak positive voltage you think is needed.

A duty cycle of 1 to 5% on a repetitive pulse should be safe
enough to avoid excess grid current. A small resistor of 1 to
100 Ohms inserted at the "bottom" of the grid return resistor
can show the grid current measured as a voltage drop and
displayed on one channel of a dual-channel oscilloscope.
The other channel can show the grid pulse voltage. Both
channels would be DC-coupled.

Measurements would be manual and thus a lot of notation
by hand. The plate (and screen) voltages could be made
variable to see the effects of plate potential on the control
grid current in the positive region. That yields a good
baseline of positive-potential grid bias characteristics to use
in any analysis...for one particular vacuum tube.

There is no absolute "rule" on tube grid current in the positive region. Various tube type geometries differ quite a bit from one another...one of the "charms" of "old world" circuit design. :-)

For another, newer reference text I would suggest "Pulse, Digital, and Swtiching Waveforms" by Jacob Millman and Herbert Taub, Prentice-Hall 1965. That text covers both vacuum tubes and semiconductors, including positive-grid voltage conditions in tubes.

>
> Take your pick based on cost and availability. Do you already
> have a charger for one or the other?

Other considerations... Portable vs stationary? Stationary it is
almost impossible to beat the price/performance of flooded
lead-acid. Adding water allows one to compensate for electrolyte
loss due to overcharge. Of course then you MUST do the
maintenance... Going maint-free means you loose that advantage.
Flooded are still more robust re. overcharge. Once you go to any
gelled or starved electrolyte cell, you don't want to overcharge
because if the electrolyte boils off, your battery is damaged.

lead-acid is usually cheaper energy storage. NiCd is lighter weight
(physically) for the same storage capacity but costs more. NiMH is
lighter still and costs more than NiCd (but the price difference is
rapidly decreasing). Lead-acid is damaged by being left less than
100% charged but Ni?? doesn't care. NiCd and NiMH can be easily
damaged by being overcharged. NiCd is one of the best at accepting
high charge rates (1C is typical and even higher rates can often be
used) as long as the charge is terminated when complete or if the
cell heats excessively. NiMH is almost as good. Lead-acid usually
doesn't like charge rates above about C/5 and usually only flooded
cells and some AGM can tolerate that fast.

As Mike said, you might think about making it as sensitive as you reasonably can, and using attenuators to get to the full scale you want.

With passive detector circuits (diodes), you'll have trouble getting below about 100uV minimum sensitivity. It's possible to do a bit better, but not much (especially not with a "cobbled" solution). On the other hand, with half a watt radiated and only 10 feet away, you should have no trouble picking up many millivolts, with the right probe. You didn't mention the frequency...if it's below 100MHz, 10 feet will be near-field and the magnetic and electric fields won't as a rule be in the far-field 377-ohm ratio, so there may be significant differences between electric and magnetic field probes. At 1GHz, a 1/4 wave whip receiving antenna should get you roughly 40 millivolts into 50 ohms, 10 feet from a half-watt source.

Analog Devices (and others now, too, I believe) make some sensitive active RF detector chips that will give you an output voltage linearly proportional to the log of the input voltage: linear in dB. That seems the easy way to go if they cover your desired frequency range. Some time ago, I did a similar thing with a Schottky diode detector and a very low input bias, very low offset op amp connected as a log amplifier, but now I'd probably use one of the AD parts. You likely wouldn't need an attuator, because you can get several tens of dB range with them.

And of course, there's a lot to be said for just trying it and seeing what you get.

Cheers,
Tom

Another book to look for is the one from the MIT/RadLab series which
deals with vacuum tube characteristics. My uncle showed me the
section he wrote, which happened to deal specifically with
electrometer tubes and characterization of the grid current for them,
so I know it's in there. Sorry I can't give a more exact reference.

Cheers,
Tom

Check out Elecraft, http://www.elecraft.com/,
the K2 has most of what you are looking for except I believe the AM/FM
capability.

Also try http://www.warc.org.uk/cdg2000%20files/release1/CDG2000.htm
which I believe is in RSGB.

If you are doing it yourself, how difficult it is depends a fair bit on the
performance you want.
ADI is making a DDS that clocks at 300 MHz and I believe they have one a 1 GHz
now
- a little power hungry for "mobile"

QST Dec, 1981 has "A Modern Upconverting General-Coverage Receiver"
has AM & SSB.

Brethren,

I want to put a cheapo general coverage HF RX on my car,
and use a whip antenna, CB-length at most.

I have noticed that in my area FM TV and AM RF fields are so
ridiculously intense that even professional active antennas have a
hard time coping with them. In fact, even good quality car radios
have a hard time getting anything unless you REMOVE THE ANTENNA.

Before I embark on building a complicated wideband high-intercept
point matching preamp, which may turn out to be unusable, I wonder if
anyone knows how to design a contraption with these features:

5-20 MHz BANDPASS, A BIT OF ATTENUATION OF AM AND FM BC

INPUT MATCHING A SHORT WHIP (3-5 ft)

OUTPUT INTO 50 OHM

I am tempted to design something of this kind:

1) Pi network, fc=2.5MHz, Zi=Zo=800 ohm

2) Wideband stepdown RF transformer, Zi=800ohm, Zo=200ohm

3) T network, Fc=40MHz, Zi=Zo=200ohm

4) Wideband stepdown RF transformer, Zi=200ohm, Zo=50ohm

[for both 2 and 4:
winding ratio = 2 to 1
ZLi >= 3 times Zi @ 9MHz]

5) Wideband amp at 50 ohm for ham signals,
or nothing for major broadcasters.

What do you think?

BR, & TIA from Milan

Yeah, in a pig's eye....

Think of avionics:
it's FORBIDDEN to use cellphones on planes, although the avionics
should be immune from out-of band signals.

I thought this was bullshit until I had a truly bizarre incident.

I was at Boston Logan, flying out to Chicago, and I carried an old,
supposedly high quality, European GSM phone, ___900 MHz ONLY___.

On arrival, not only I discovered that my thoroughly unusable phone
(which I had kept off for a week) had switched on accidentally in my
bag. IT ALSO HAD RECEIVED A TEXT MESSAGE FROM ITALY. I later checked
with my provider, who confirmed that a message was delivered while I
was in the US.

This means it managed a successful RF and protocol handshake,
validation, and transaction, on a frequency is was not at all supposed
to cover.

I can only guess that I was very close to a 800 MHz US GSM BTS, and
that signals somehow broke thru out of band both ways.

From then on, I took the airline cellphone ban much more seriously,
and claims of spectral purity much less so!

==========
Perhaps it is worthwhile mentioning that ,especially NiMH batteries have a
relatively high 'self discharge' rate.
To be ready for delivering energy on demand at all times continuous trickle
charging ,when not in portable use, is recommended . The same applies to
NiCads being it that their self discharge is somewhat less.

The US has some 900MHz GSM networks, so your phone may well
have just been doing what it should.

There were some tests done on commercial aircraft for field strengths
from various sources, including the use of cellular phones. The
largest
field strength in the cabin by a very large margin was leakage from
the
microwave ovens.

However, use of mobile phones is an unnecessary extra risk, and could also cause network problems (hand-off assumptions in the network don't include 600mph speeds, and the large coverage due to the extra height could be a problem).

> 30MHz and under, though specifically it's initial (and perhaps only)
> use is for a 10 meter beacon.
=========
That means you need a socalled TVI filter cutting off frequencies above say
40 MHz

This filter is described in ARRL Handbook (the latest one I have is from
1995)

In the above publication LP filters are described on page 10.21 and the
specific TVI filter parameters can be found on page 30.22
The filter dimensions indicate use in high output transmitters , but for QRP
(or in your case a power level of 20 Watts) the required inductors can be
readily made with suitable toroids with the inductance to be checked at the
operating frequency with for example a MFJ-259B antenna analyser. If you
have access to such an instrument ,the completed filter can then be assessed
with a spectrum analyser .

I am sure this type of LP filter is also included in more recent ARRL
Handbooks ,since its purpose is to prevent TVI caused by HF transmitters.

Good Luck

Frank gm0csz.kn6wh@ntlworld.com

> I have noticed that in my area FM TV and AM RF fields are so
> ridiculously intense that even professional active antennas have a
> hard time coping with them. In fact, even good quality car radios
> have a hard time getting anything unless you REMOVE THE ANTENNA.
==========
If you don't get interference when the antenna is removed you can insert a Band Pass filter which attenuates freqs below say 2 MHz (to suppress medium wave AM sigs) and attenuates VHF sigs above say 40 MHz from TV-band 1 -and FM BC stations).
In fact a combination of a High Pass - and a Low Pass - filter.

These filters are explained and described in ,among others, the ARRL handbooks.

The filter should be fully enclosed in metal (properly bonded to the car chassis with the shortest possible strap) and connected to HF radio and antenna via good quality coax cable.

sci.electronics.cad might be a better place for this. All the SPICE experts
tend to lurk there.

==========
Perhaps it is useful to refer to an article in QST- June 2001 (p 38 -43) :
Simple RF-Power Measurement ,by Wes Hayward ,W7ZOI & Bob Larkin, W7PUA ,
employing the Analog Devices Log Amp chip AN8307 (0.1 -500 MHz) with a
sensitivity
of better than - 65 dBm . This (home brew) instrument fitted with a short
whip could
serve as a sensitive relative field strength meter.
Analog Devices supply free samples of this and other chips.

Hi,

I can't seem to get a BC337 to provide any worthwhile voltage gain
with any signal over about 200Khz. However, the quoted transition
frequency for this device is 200Mhz. Anyone have any ideas as to what
the problem might be? Surely I'm not expecting too much of the BC337
at such a low frequency?

I remember that article; it was a pretty good unit. I believe that the author of that article used a hybrid design, premixing a VFO with the synthesizer, using thumbwheel switches for band selection. I have come up with a newer design that uses off the shelf parts, and would be glad to forward that info to interested parties. I know that I do mention this from time to time, but there still seems to be some interest in this design.

>GHz now - a little power hungry for "mobile"

The following is a quote from this morning's RF Design magazine
e-mail newsletter that might be worth investigating:

==========

RF Design Staff
Norwood, Mass. -- Analog Devices Inc., a developer of semiconductors for signal processing applications introduced its new family of direct digital synthesizers (DDS):

• The AD9951 -- a basic DDS with on-board 14-bit DAC,
• The AD9952 with high-speed comparator,
• The AD9953 with RAM, which allows nonlinear phase and frequency sweeping, and
• The AD9954 with high-speed comparator, RAM and automatic linear frequency sweep.

According to the company, the new chips deliver a 400 MHz clock speed at one-tenth the power consumption of previous systems. If true, it would enable designers to use DDS for fast-frequency hopping at higher output frequencies in more power-sensitive applications. Typical applications include satellite communications, broadband networking, radar, test and measurement, and instrumentation.

Analog Devices also says its new DDS devices are the first in the industry to clock at 400 Msps and synthesize frequencies of up to 160 MHz, while dissipating less than 200 mW of power. With this advancement, designers can use multiple chips on a single PCB with less concern for thermal issues, the company says.

All parts are available now in 48-lead EPAD-TQFP packages and are priced per unit in 1,000-piece quantities as follows:

• AD9951 -- $13.75,
• AD9952 -- $15.50;
• AD9953 -- $14.75; and
• AD9954 -- $17.25.

The components around the BC337 are limiting the frequency response and
perhaps the circuit configuration, whatever it may be.

If the device's power supply pins are decoupled properly, perhaps your signal is getting reduced by an unintentional low-pass filter created by both intentional and parasitic circuit elements. At these frequencies, parasitic capacitance and skin effect can create a very effective low-pass filter. Impedance of the source, input, and transmission line connecting them should match, as well as the output, load, and transmission line connecting these elements.

We cannot possibly determine the problem without details of how you are
using the device. For 1 transistor, you could manage an ASCII art
schematic, if you take one of Win Hill's as a tutorial.

How much voltage gain is 'worthwhile'?

Use the LIB part, fill in the blank for the Drive/Path/Libraryname.lib

I assume LIB is available in the student version?? Charlie?

203. Getting hiss along with strong CW signals

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-09 20:36:58 UTC
From: w.harbourjr@worldnet.att.net
Message-ID: <deafe3d9.0301091236.5b3fc48d@posting.google.com>
Source record: 38703

I'm getting a hiss that accompanies very strong CW signals out of my HB 20m single conversion superhet receiver. There is no hiss on the quieter CW notes. The receiver is pretty straight forward...antenna into a SA602AN first miser, followed by a 2N2222 emitter follower amp then through a 3 4.915Mhx crystal filter terminated into 220ohms, then through a SA602AN BFO outputing differentially into a NE5532 LPF then onto a LM386 final audio amp.

Any idea where to start looking? One of the audio sections was breaking into oscillation when the strong signal arrived but I changed a few output/coupling cap values and that's largely gone away. Is the hiss a sign that I'm still getting some oscillation?

Thanks,

Bill
K4VIB

I have an RCA Radiotron; if someone needs, i would be glad to scan up
to about a dozen pages at 200DPI in GIF (most compact) and send the set
of scans (PDF and ZIP makes it larger).
Any specified page or part (like a graph) i would be then glad to scan
at higher (specify) resolution.

That 200kHz will be due to, too high a gain, capacitive loading effects,
high source resistance.

At a gain of say 10x, then the BC337 trannie is only capable of a flat
20MHz. A gain of 100 and the trannie can only do a flat 2MHz.
This assumes *no* capacitive loading across the collector resistor and that
the source or driving impedance is *very* low.

Assume your circuit has (say) a gain of x20.
This instantly sets an upper frequency limit (-3dB or 70% gain) of 10MHz.

If your design also has say a 1k collector load with 5pF of stray
capacitance across it, (quite normal) and another 5pf of 10:1 scope probe
capacitance hooked onto the collector, then this will cause a simple RC
low-pass filter, with yet another low-pass break frequency of 1/(2*pi*C*R)
this one is 16MHz.

That's 2 things we have (effects are both running together) that are now
killing the HF gain off.
Add a third! called 'Miller effect'.
This is yet another RC low-pass filter. The 'R' in this case is the
source-impedance driving the trannie. The 'C' is the trannie 'base-collector
capacitance' (plus strays) who's combined effect is stepped up by the
trannie gain (the "Miller effect" bit).
Say the actual Cbc+strays is 3pF and that your circuit is being driven from
a 50ohm sine generator. As the trannie gain is 20x then the 3pF of
collector-base capacitance has an effective value of 60pF. Yet again ...

1/(2*pi*R*C) gives the third roll-off at 53MHz.

So ... There are 3 low-pass roll-offs all at work together, 10Mhz, 16MHz and 53MHz. If you're looking at the waveform on a scope, then expect to notice the response start dropping off in the 3-5MHz area.
In your case the figure is a very low 200kHz!, which implies a designed gain of (say) x100 with a signal source of 2k7ohms or a gain of x100 with a low source R but a collector resistor of (say) 4k7 with 170pF of loading, (or any mixture of these two effects).

This stuff is the magical part of analogue design and to get a decent H.F. response you need to try a number of tricks/techniques. The easiest is to keep the gain low and design the collector resistance to be as low as possible. Keep the source impedance as low as possible. Use 'R.F' transistors with high Ft's and low collector-base capacitances. Keep the collector strays and loading capacitances as low as possible.
As an example ... a single 2N2369 trannie with a 100ohm load can run out to hundreds of MHz at low gains and small strays.
Other (more esoteric) techniques are also available, such as tuning out stray C's by means of added small inductors and the use of 'shaped' feedback.

A HF, wideband, hi-gain ampifier can be a work of art so don't be dismayed to have to use two transistors at HF when one would be OK at LF.
Also bear in mind that the two transistor 'Cascode' circuit is the best technique available for wideband HF work. (other than putting the bits on Silicon ;-)
A Spice circuit can be very useful for this kind of HF stuff, as it saves the wodge of tedious RC 'what-if' knock-on response calculations that need to be done, if one small change is made to a single transistor stage.
regards
john

save your model as a .mod file

open a new project, selecting analogue or mixed A/D

File ... new ... PSPICE Library

model ... import ... then open your model.

tools ... options ... tick "always create part when saving model"

save the model.

To place part, open dialogue as normal and import your custom library.
then place away.

node names will be as listed in your model

Simon

208. FS Svetlana 4CX1600B tube and socket

I second the MC12080D. Drive it with a sharp edge like a square
wave and it'll go even lower than 50 MHz. Great device...really
sips power (5mA Icc) unlike the ubiquitous 95H90 that would burn
your fingerprints off. Too bad Mother Batwing discontinued the
MC12080P 8 pin DIP some years back.

The differential inputs on this device, if left unterminated, will
cause the chip to oscillate at its resonant frequency. To alleviate
this, pull the inputs apart toward +Vcc and ground thru several
hundred K ohms resistance.

Celphones on planes access too many cells at one time messing up the
cellphone system. Also it is not the effect on the planes radio gear but
some of the planes are fly by wire now and the extra RF can cause them to
do strange things. A pilot friend of mine was telling about how one of the
newer jets would make a slight 'shudder movement' when it was swept by a
near by radar. It would not be noticed by the passengers but the pilots
could tell.

Hey, don't give away the secrets of those of us who stayed awake and really worked out those multi-stage transistor amplifier designs by hand!

Just kidding, although there seems to be quite a chasm between "digital" and "analog" engineers. Luckily, as circuits get faster and faster, even the digital guys (and gals) have to stay awake in those boring analog courses.

The bottom line: for circuits operating above 10kHz or so, ALWAYS consider parasitics, since they invariably add more poles (and an occasional hole) than the schematic shows.

Jeff

>
> Thanks,
>
> Al W6LX

The Bird 43 instruction manual has a freq response graph for the 100 to 250 mhz 10, 100 and 1,000 watt slugs only but says that the curves are typical for all slugs (A,B,C,D and E) at their respective stated frequencies. Accordingly, extrapolation can be assumed which is useful when measuring harmonic signals outside the specified frequency range of the slug.

The low power slug (10 W) is down 1 dB at 74 and 380 mhz. and 3 db down at 48 and 560 mhz.

The medium power slug (100 W) is down 1 db at 38 and 460 mhz and 3 db down at 20 and 800 mhz.

The high power slug (1,000 W) is 1 db down at 20 and 1,000 mhz. There is no 3 db info.

Analog Devices just announced the 9951, which clocks at over 300 MHz and
uses only 1/10 the power of their previous device (9854?). Requires 200
mW of power.

It is a 14 bit device, but I still think you need something to clean it
up for receiver use.

You have to enter each channel into the scan list then it will scan.
Look for SCH on the number pad label. Choose the channel you want to
scan, you will need more than one, and while pressing Function, press
SCH to add that channel to the scan list.

As you press the Function / SCH you will see little channel numbers
appear across the top of the radio. This is the indication the channel
is included in the scan list. Just press Function/SCH until the
channel you have on the display appear in that list across the top of
the display.

hey all,
I'm somewhat knowledgeable about electronics but know nothing about circuitry... I know a little about RF but not much... I would like to become comfortable enough so I can take apart old radios and change their frequencies, generally make new stuff out of old parts, etc... Any suggestions on books that would help me learn the basics of how receivers/transmitters and transceivers are built, general theory, etc?

thanks!

I have no idea; I can't even remember noticing it before, though
I knew about the Exar 2208 that started out as the Intersil 2208.

Take note that it's essence is nothing more than a "Gilbert Cell"
mixer, so common in ICs when a double-balanced mixer is called for.
If you aren't repairing something (or even if you are, by making
some changes), there are plenty of such mixers that would do
basically the same thing, the MC1496, the NE602, the Exar 2208,
all kinds of ICs that use the scheme in their FM detectors and
mixers, and even the MC1350. Of course, that isn't dealing with
levels and other specs, or even exactly what you can control
from outside; I'm just saying the basic mixer is available in all
kinds of ICs.

The most obvious difference about the 2208 and the 2228 is
that it includes an op-amp stage within the package, but unconnected
to the multiplier. The former also has a buffer stage on the output
of the multiplier. Since the 2208 seems to have been more
visible, perhaps it can be found even now.

You might want to be specific about what you need it for.

Press release is at
http://www.analog.com/Analog_Root/sitePage/mainSectionContent/0,2132,level4%253D%25252D1%2526ContentID%253D17650%2526level1%253D292%2526level2%253D%25252D1%2526level3%253D%25252D1,00.html

There are a group of devices, AD9951 - AD9954
They run on 1.8 V with 400 MHz clock yielding upto 160 MHz output signal
40% of Fclk - which is a typical number to ease filter aliasing requirements

Some NS PLL chips are available from Farnell. They are all surface-mount, so harder to use. They go up to 500 MHz or so. They are worth considering in place of the Mot. ones.

Well, you've obviously amassed a formidable expertise in RF circuit
behavior judging by that posting! I'm grateful for the tips from you
and others who've contributed here. One point arises, however: is the
chief determining parameter of the maximum frequency a transistor can
handle its base/collector capacitance (both intrinsic and external)?
I mean, could one get a good idea of how fast an RF tranny is just by
the manufacturer's figure for intrinsic b/c capacitance? I'm assuming
such a figure is also a SPICE parameter?

IIRC I bought my copy in 1954 or 1955 at the age of 14 or 15, about
when I built my first Williamson (I think that's what the tube amp
with screen taps from the output transformer was called ??).

From: Al Gerbens <agerbens@msn.com>
Message-ID: <OQjo9LMuCHA.1444@cpimsnntpa03>
Source record: 38732

Any ideas on how to make small rectangular holes , say for slide switches,
in plastic enclosures?

233. Re: Rectangular holes

Newsgroup: rec.radio.amateur.homebrew

Hello,

Mark the outside limits with an pen.
With an drill make an hole smaller than the outside limits
With an rasp remove the plastic till the marks.
Finish with sandpaper.

This worked for me although in aluminum.

Mmm... Hot knife? A heated Xacto blade, to be specific.

Drill a small (3/16") hole in the center of where the rectangular opening goes.

then, use (purchase) a hand nibbler tool. They are indispensible!

A hot knife tends to leave a raised ridge around the opening, which
may then need to be removed.

A drill and a nibbler tool will be faster, neater, and you'll be ready
for aluminum enclosures later.

A decent nibbler tool will be $15-20.

To be honest, I've only casual knowledge in this interesting area of circuit design!. I've noticed though, a couple of this group's posters are -real- RF men and should have some good angles. As Jeff V mentioned, fluency with it comes from actually doing it and as is usually the case, the best learning come from figuring out why the stuff won't play ball.
To a first guess the Ccb value is a very good pointer to a fast transistor but it is one of a host of other internal transistor factors that are waiting in the wings and ready to pounce. All the factors come into play at some point as the frequency moves upwards.
For HF use it's usually best in the first instance, to select a transistor from the lists specifically marked as 'RF' transistors. This ensures that most of the major, internal limiting factors, (particularly internal capacitances), will have been characterised and optimised to allow more predictable operation at the higher frequencies.
Yes, the Ccb is an essential spice model value.
regards
john

Incidentally ... What was your rough gain and source impedance?.

No, the Williamson was earlier and used KT66 pentodes connected as
triodes. Your amp, using the 'ultra-linear' screen feedback trick,
might have been the Mullard 5/20, the GEC 912 or the GEC 88-50, if it
was a British home-constructor design.

A lot of the stuff you've been told is more applicable to operation at
20 MHz than 200 kHz. I still say that if you want the correct solution,
you should give more information, preferably a schematic.

Ccb of a small-signal silicon bipolar is NOT a factor at 200 kHz. Unless
you have a 1 Mohm source, of course, and/or a voltage gain of 100.
That's why we need more data.

Not necessarily. Meisei Corporation makes an adjustable-temperature hot knife that most often finds use in wire-stripping operations. If you set the temperature right, it'll be just enough to go through the plastic cleanly, and not melt the sides thus creating a ridge.

> A drill and a nibbler tool will be faster, neater, and you'll be ready

No argument there. I just didn't happen to think of a nibbler when I saw the original post.

I remember those - a real pain to mount on a 1/8" aluminum heat sink. One hole for the mounting stud, then three for the leads. My holes usually got too big after moving them over to fit the pins:)

Mike

247. FS: LCD 16 x 4 displays, $6 each. NEW! MUST SELL!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-10 22:41:29 UTC
From: ovrreactor@aol.com
Message-ID: <20030110174129.02142.00000115@mb-df.aol.com>
Source record: 38646

I am selling BRAND NEW LCD display modules, made by Data Vision, model number DV-16400 (reflective, no backlight). Asking $6 each (please order in increments of 6). I have 85 of these on hand.

NOTE: This model is still in production, so manufacturers can design this part in, and be confident that additional stock can be purchased through distribution later.

Picture, detailed PDF documentation, and manufacturer website link is available at;
http://members.aol.com/ecc81/yardsale

If you need larger quantities, I might have a few hundred more buried in my storage unit. Let me know if you need more than 85, and I'll dig around for them.

Please respond BY EMAIL (do NOT post) to < OvrReactor@aol.com > if interested.

Thanks,
Tom Mitchell

I was lucky. My father-in-law-to-be ran a machine shop. He machined
me the most beautiful heat sink you've ever seen ;-)

He also planed the head on my '53 Hudson Jet after I warped it by
over-heating the engine and blowing the head gasket. Made it pretty
speedy... I could get 100MPH out of it ;-)

What's the application, common emitter, common base, common collector, class C, class D, class S, etc? Depending on application, Ccb may be most important, hoe may be a factor, etc. In most cases, the most important factors may be experimentally determined by playing with the parameters in SPICE, but that's just one possible starting point.

More info is needed.

Commercially, I used a local signwriter who has an X-Y laser cutter.
This produces perfect holes, ANY shape, with exact clean edges
up to 5 mm material. They need a DXF Autocad file of the lines to cut.

Simple. Clean. Perfect.

The down-side ?
For small runs, they may charge a setup cost.

I could only get about 90 or so in my Dad's '49 Ford Flathead, no matter how much I tweaked the carb screws.

I saw one recently in Fry's parking lot in Santa Clara. Could not figure out how my girlfriend and I could both fit in the back seat. Not sitting up. Well, you know what I mean:)

There are always some commercial equipment that can do a great job,
flawlessly, in seconds.

But no individual without a business would ever get one of them.

I don't want to speak too hastily, but I think that Exar doesn't do this
stuff anymore (I have some XR2215's from the early 1980's hanging around.).

Analog has a couple multipliers -- AD633 and AD834.

Now we're bringing back the remembrances... I had a '50 Nash where the
front seat folded down to make a near-full-size bed ;-)

And the vibrator-powered tube radio would run the battery down in less
than an hour, so you had to park on a hill (fortunately easy to find
in West Virginia).

In my senior year in high school I got a '53 Packard (straight 8),
that car would haul ass! My father sold it while I was at MIT... my
sister was too short to drive it :-(

Draw your perimeter. Dril hole inside, say 3 mm. Use a jeweler's saw (a U shaped one with a fine blade). Don't drink alcohol within ten hours before this surgery (;-)). Then use your fine file set. Works great both in aluminium and plastic.
Cheers,
Harke

You might also want to put some sort of resistive termination at the antenna
end of the filter, to eliminate some of the interraction of your auto
antenna.

=======
Bought a nibbler a few years ago from Ratshack $ 9.99 A very useful
tool ,but meant for metal holes.
For small sliding switches the tool is too big.
For plastic holes I also would use a hot knife ,filing the opening to size.
For metal (small) holes I would drill 0.125 in. holes inside corners and use
thin removable jig saw blades (clamped in U-shaped saw handle ,for cut out .

Hi Steve,

I'm afraid that I don't know of any direct replacement for the Eico test port connectors. I have a few old probes from my Eico sig gen and Eico sweeper that are badly in need of replacement. What I have done is to replace the output ports on my Eicos with easier to find BNC ports. Now I don't have to worry about the old Eico probes and their difficult to find parts.

Hi,

I was just starting to piece together a breadboard circuit for an RF field strength meter when I happened to notice that keying the low-power transmitter under test (half a Watt out) resulted in a substantial waveform being displayed on my 'scope about 6 feet away (just by induction through the probe lead, I imagine). The question then arose as to whether I needed to build a FSM at all, since the 'scope is obviously sensitive enough on its own to pick up highly local transmissions.
So I'd like to invite views on whether this is feasible or not. I can't see a problem with it, but maybe someone else can. Any ideas, gentlemen?

I'm impressed, nonetheless.

>Incidentally ... What was your rough gain and source impedance?.

Unity and zero respectively.
Confused? Understandable. It's a Spice simulation. I was aiming to get
a reasonable gain at the required 40Mhz, but there was zilch output.
But everything was fine at 20Khz. I therefore decided to up the
frequency of the voltage source to establish where the gain began to
fall away and this is where the 200Khz comes from. For some reason I
couldn't get the AC sweep to work so had to do it manually - a *real*
drag!

>That's why we need more data.

Yes, I appreciate that. Perhaps if Virgin ever get around to fixing up
their lousy service I might be able to post a schematic. But it's
really only a very simple single-stage test circuit; just a transistor
+ bias network to establish where the gain begins to fall away.
There's precious little if anything to account for the stage's
sluggish performance.

Thanks, Jeff. It's common emitter config. in class A; just the initial
stage of an RF rx preamp. Yes, I know you're probably going to say
throw the BJT away and use a FET, but this is of more academic
importance to me now - getting to the bottom of it.

Hello all,

If anyone is looking for a splendid simple FM receiver, I have one.

I call it the 'Radio Shack Special', since all of the items may be purchased there. I tried to make this project interesting...by not having to mail order any one component. I surrender this project to all.

The sensitivity, selectivity and great audio is second to none. Read what others had said about the project at the website. All are warmly welcome.

The site is at: http://braincambre500.freeservers.com

Respectfully,

Patrick Cambre

==========
A FSM usually needs to be a portable device to test antennas in the (near)
field and unless you have a small portable LCD scope a more traditional
instrument with a moving coil meter or LED bar seems more appropriate.

The 'non inductive' resistors have the resistive film in a serpentine rather
than a helical form so that the inductances cancel. The manufacturer should
be able to give a plot of impedance vs frequency.
Farnell is a distributor, who is the manufacturer?

Good day to all!

Looking for some Ramsey WEFAX weather satellite reception equipment.
I'm not sure all what came with the orignal package when it was bought
new from Ramsey, but as far as I remember I should be looking for the
weather receiver and the PC card.

if anything, links to where I could build my own 136-138MHz 45KHz wide-
bandwidth receiver would also be good.

Appreciate it!

There are various cutters for Dremel and other small rotary hand
tools. They work _reasonably_ well, although you shouldn't expect
straight edges or square corners. But they're good for an initial
rough cut on a not-too-small rectangular hole.

On plastic, you want to keep the speed and force down, or you'll
melt plastic and form a ridge which then has to be ground down.

Blimey it's with it's original box and packing !
I've converted more of them than the pope.
You can take them up to 29MHz without an eprom or crystal change,
but you need a eprom or 4008 binary adder if you want the 100KHz rpt shift,
and you can switch the 10KHz reference to 5KHz, giving 5KHz steps

It's well worth putting in the missing 2nd If transformer,
and the missing noise sq cct, as fitted to the JWR M2 version.
also produced as the Lucas 1001

SWM was the first to publish mods for it in 1982

The BC337 certainly WON'T work at 40 MHz, but I still don't see why you
have a problem at 200 kHz. Why won't you post the schematic?

Yes - but you must mount them on a heatsink, so you need to be careful
about the shunt capacitance of a few pF.

I covered this topic extensively in 'In Practice' for June 2002 with a
follow-up in October which said:

John Fielding, ZS5JF, e-mailed with a report of some measurements he
made about five years ago using a vector network analyser (VNA). "Using
a SMA connector with very short leads connected to the sample resistor -
a 100W part made by Craddock - I was amazed to see a perfect 2:1 SWR
right up to 3GHz! Later I obtained some 50 ohm resistors from the same
source and they also behaved perfectly up to 3GHz, the limit of the VNA.
However performance degraded badly when bolted to a heatsink, due to the
capacitive coupling between the flange and the heatsink. As I recall
the SWR was better with the leads connected one way than the other. We
eventually used these resistors as a 50W dummy load for a 30-88MHz
transceiver for 'silent tuning' and they were more than satisfactory.
They are certainly a lot cheaper than the pukka RF load resistors sold
by other firms. When properly heatsinked they will work OK up to about
432MHz at the full rated power." .

Please quote a typical Farnell order code. I looked for them and
couldn't find them, which is why I posted a question here about sources.

If they do a 50 ohm, it must be intended for use as a termination,
because 50 ohms is not a preferred value (47, 51, 56).

The only problem is determining what you're measuring the field strength of. Chances are that your rig isn't tremenously well shielded, so at six feet away, the scope is likely measuring leakage through the box or from power leads, headphone wires, or other wires leaving the box. Although you can tell the rig is generating a signal, the relationship between what you're seeing on the scope and the signal being radiated from the antenna might not be as direct as you'd like.

If you're seeing a signal without the probe being attached to anything indicates that the signal is entering the scope via a path the scope isn't really intended for, such as its power cable or around its shielding. This means that the attenuator might not give the attenuation you expect, making it difficult to make even comparative measurements unless you stay on the same scope scale.

These problems aren't because of the scope, which is just fine as a detector (although it won't have the dynamic range or shielding of a good FSM, if those are important). The problem is the proximity of the detector to the rig. To get a good idea of how much signal is getting radiated from the antenna, you've got to put the detector far enough from the rig that the signal from the antenna is much stronger than leakage from the rig and its re-radiation from local conductors. And, in the case of the scope, you'd also have to connect the input to an antenna that will receive a much larger signal than will leak in via other paths.

Nice thing about the scope is that it gives you
some idea
of the dynamics of the signal. Amplitude
modulation, big spurs,
general badness, that you won't see on a field
strength meter.
Won't help much on low level harmonics unless you
do a FFT on it.
If you put any sort of antenna on the scope input,
it will often
swamp out any signal that's coming in thru other
leakage paths...at least
on a quailty scope. Easy to check by pulling off
the antenna.

==========
Caddock -Riverside , California is one of the manufacturers making these
resistors

Their 'KoolTab' models MP820 and 821 parts are in a TO-220 package with
values between 10 and 10000 Ohms and are very suitable for dummy loads and
as the input resistor(s) of valve (tube) type RF linear power amplifiers .
If fitted on a suitable heat sink max power dissipation is 20 Watts .
Standard items have a tolerance of 1%.

From 0.4 -100 MHz SWR = 1 : 1
at 500 MHz SWR = 1 : 1.04
at 1000 MHz SWR = 1 : 1.37
These SWR measurements have been made by someone in Germany ,using a Rhode &
Schwarz ,Scalar Network Analyser and sweep generator 0.4 - 2500 MHz

I've found a fret saw with a fine tooth blade and the work clamped firmly
can do a good job. It's particularly useful for slots that are narrower
than the nibbler.

Try 306-6952, 100R 50W (omit the hyphen when searching the Farnell web
site... duh...)

The 50W range is better value for money than the 20W.

I asked Farnell for more details of the RF performance, but they don't
have any more useful information than is given in the brief catalogue
description.

>If they do a 50 ohm, it must be intended for use as a termination,
>because 50 ohms is not a preferred value (47, 51, 56).

The catalogue dealers do not stock all preferred values (not even the
full E6 range). If you don't mind the extra capacitance, two 100R units
in parallel will give more dissipation and better spreading of the heat
load.

One way to deal with the stray capacitance is to make it act as the "C2"
of a symmetrical pi-network. In other words, you connect to the
resistors with a small shunt C (equal to the value you're trying to
compensate in the resistors) and a small series L. In practice, the
shunt input C is variable, and is adjusted for lowest VSWR.

This network forms a lowpass filter with a 1:1 impedance transformation,
and is transparent to low frequencies. At higher frequencies, a bit of
modelling will show how the stray reactances can be compensated exactly
at one chosen frequency; the tradeoff is a small increase in VSWR at
lower frequencies, but a steep rise above the compensation point.

I covered this in my November 2002 column, in the context of
compensating the input capacitance of a tetrode operated in 'passive
grid' (with a tube input capacitance of 30-50pF).

They make a special kind of knife for cutting Plexiglas which works well on some holes, but in the specific case of a slide switch, I don't think it would work all that well. I'd be inclined to stick with the X-Acto knife for a hole that small.

For many larger holes, LCD's and the like, I avoid the problem altogether by making a panel from Plexiglas and backing it with paper containing my labels etc. It's a lot easier to cut a hole in paper than plastic! Scraps of plexi adequate for panels are often available very cheaply at the hardware store. Glossy paper makes nice crisp lettering and isn't obviously paper behind the panel.

What do you use to amplify small DC voltages?

The trouble with amplifying DC voltage is the interference from DC offsets in the amplifier. While you can use a high-pass filter to remove the DC offset for an amplifier in the audio or higher frequencies, this is not an option for DC, as this would attenuate the DC signal as much as the DC offset.

Thank you. That steered me to the right page in the hard-copy catalogue.
I only need 0.5 W rating, so the 5 watt MCP series will do: I haven't
all that much room, or budget!

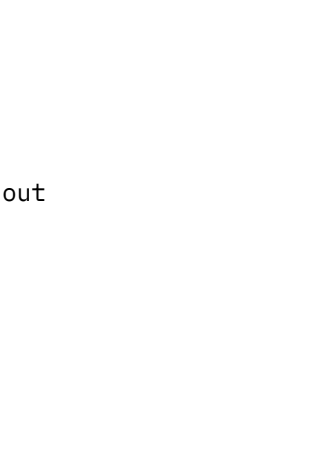
The BC337 is a respectable and popular transistor. A web search shows huge quantities available on distributors shelves at very low prices, from at least 12 different semi manufacturers (e.g., Newark has 10179 available of ON Semi parts for 5 cents, qty 1k).

According to the Siemens data sheet, the BC337 has f_T over 100MHz for collector currents from 7 to 170mA with Vce=5V, and an f_T of 180MHz at 50mA. ON semi's data sheet shows its Ccb capacitance is only 5pF at 5V. So BC337 transistors can make a 40MHz amplifier, especially if several are used. It's entirely a matter of your specific circuit design. For example, this simple circuit biases the BC337 near 20mA and 5V, and is intended for use with a 50-ohm source and load. At 200kHz and below its voltage gain should be about 35 to 40, if my back-of-the-envelope is working. It should still have a gain of say 2 or so by 40MHz (a more complex circuit could have a "flat" gain to 40MHz).



Tell us about your design, the collector current, load resistance, the bias setup, emitter resistor and bypassing if any, etc., etc.

What spice software are you using? Post your BC337 model for us;
let's get to the bottom of this "zilch" business. :>)

Thanks,
- Win

```

In real life a BC337 would be OK with these values, because 20mA * 5V = 100mW, and a thermal resistance of about 200C/W means its junction temp would rise by a modest 20C.

Thanks,
- Win

Use a chopper stabilized opamp such as the TLC2652A by Texas Instrument.
It has a 1uV max offset voltage only.

Electronic engineers use chopper amplifiers, and physicists modulate the source of the DC, and selectively amplify and detect the modulated output -basically the same idea as a chopper amplifier.

Horowitz and (Win) Hill's "The Art of Electronics" ISBN: 0521370957 has a useful chapter on this sort of stuff.

Depends on what you consider 'small'. You can buy cheap opamps with
offsets of a few millivolts, and drifts on the order of 10 uV per
degree C. Or really good chopper opamps that are roughly 1000:1
better. At very low levels, thermoelectric effects, stray RF, leakage,
noise, and magnetic fields get to be annoying.

John

Which is the level of the voltage you want to amplify?

There are opamps with almost zero DC offsets that can be used for
small voltages - say, up to 10V maximum.

Take a look at:

www.linear.com
www.analog.com

among others, and compare precision opamps.

Jorge

Some ham radio clubs may help an interested person learn
enough to get their license. If you find such a friendly
group (not as common as in years past) the informal
education may be what you need to get started.
Don't expect it to be quick though. Learning by hobby is not
the fast route to education.
A search of Amateur Radio related websites should be enough
to tell if this is what you want. The ARRL should be the
best source.

314. Transistor substitute?

I'm trying to locate a substitute for a TP9383 RF power transistor.

My Jaeger sub book does not list any.

I wonder if anyone can suggest anything?

This is the final output device in an early Rohde & Schwarz 50w FM
broadcast exciter.

Thank you.

No transmitter is broke forever, maybe tell us what type and model and what he need to get the rig back up. It's a lot easier to ship a few parts than a complete xmitter.

Another point, there is always an endless supply of advice on how to repair theses things.

Lets have a few details

I think you might want to start tracing with a good scope to see
exactly what is going on, and at what stage the problem is
developing. Kind of hard to second guess the cause. You could
try using an outboard amp. and see if the problem persists, or
use the outboard amp as a signal tracer along the AF signal
path.

A few moments poking around at Yahoo revealed that the M9583:
i) is or was a Motorola VHF power transistor
ii) was used in the Maxor 80 (160MHz transceiver) PA stage
specifically the TLD9102A and 9103A power amp boards
iii) had a power output rating of ca. 25-30 watts
iv) had Motorola part number 48-869583
or S-48-869583IMS
v) is almost certainly obsolete
vi) is possibly still available in the surplus market. See
http://www.downeastmicrowave.com/Surplus.htm
vii) may have substitutes, but you are on your own here.

Good luck and 73

The ambit 8KHz 10.695 2 pole Xtal filters are a bit sharp for 10FM

Something like a cheap 10M30 10.7 +-15KHz Xtal filter will do fine,
which works out as -10 +20KHz at 10.695,
or even a 50KHZ 10.7 ceramic filter if you can still get them ?

Anything's better than the 150KHz ceramic filter they use
to protect the internal 2nd mixer in the MC3357 chip

and dig out a Toko 7mm 455 IFT from a scrap tranny radio,
for where they've left it out on the end of the CFU455 filter
in the ICOM 1050, but fitted in the JWR M2 version.
It improves 455 filtering outside the CFU ceramic filters B/W
and gives a better match to it

Steve Terry

324. VariL CM-1 DBM as used in R7/TR7

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-13 09:05:31 UTC
From: no.spam.lasse.moell@no.spam.swipnet.se
Message-ID: <3e227f0f.653908@news.lin.foa.se>
Source record: 38622

Someone asked for data on the 1:st mixer used in theTR7/R7 radios and
said it was labeled as Vari-L CM1.
Their databook says:
CM-1 Low cost Miniature Double Balanced Mixer .5-500 MHz
LO Power Range +4 to +13 dBm
1 dB Compression Point 0 dBm
1 dB Desensitization Point -2 dBm
3rd Order Intercept Point +13 dBm
Isolation typ. R-X 30 dB 1-100 MHz, L-R, L-X >50 dB 1-100 MHz (as read
from graphs)

Pin Connections:
LO 8
RF 1
IF 3,4
Ground 2, 5,6,7
Case 2
Note pins 3 and 4 must be connected together
all ground pins must be grounded

I can do a pdf on the complete specs if required.

Cheers
Lasse SM5GLC

325. RF feedback, anyone?

Hi,

Let's say I have a hand-held transmitter operating on 40Mhz. I take a 'sample' signal from it and feed it via a 6 foot cable to a separate low power linear amplifier. It's then fed back via a different wire in the same cable to the tx for transmission from the tx's antenna. Let's say the 'sample' RF is 2v peak-peak and the return, amplified signal is 20v p-p. Can I get away with this or am I likely to have problems with feedback owing to the wires being in such close proximity? Would using shielding on one or both of the wires help if this set-up is likely to cause problems?

Which is precisely what I'd intended to do.
So far as the problem of capacitive effects from adding heat-sinking,
how about having no metallic heat-sinking at all and simply immersing
the devices as they are in a sealed can of oil?

```

Ran a spice response plot of my circuit above. Showed gain of
16.0 flat to 3MHz, down 3dB at 10MHz. Gain = 3.88 at 40MHz
for our BC337 with 50-ohm source and load. That indicates an
f_T better than 155MHz for the spice part model at 20mA and 5V.

Thanks,
- Win

I use a chopper amp from TI in a pH meter. A good source to check is Analog Devices or Texas Instruments (which now owns Burr-Brown.) In particular, ADI has an application note on "finding the needle in a haystack".

Other things to consider -- at small, very small voltages, every node potentially picks up radio frequency interference, computer noise etc -- you want top and bottom ground planes, decoupling of the power supply, isolation of digital and analog grounds etc. -- again see the apnotes at TI on ADC selection since the info there will speed your quest.

Very nice Paul, good first try! I removed some extra spaces,
tabs?, etc., whatever, to make it viewable with a fixed font.

OK, ran a spice plot of this. The low input capacitor value means
it's having difficulty with frequencies below 1.6kHz - it reaches
a gain of +45dB and is flat from 5 to 40kHz. It's down -3dB by
107kHz, and has no gain at 40MHz as you observed. That's because
you've got the BC337 running starved at Ic = 80uA and Vce = 0.76V,
and with a high 150k load (note my comments on the effect of Cob).
Note my post a few minutes ago showing a gain of about 4x for the
BC337 at 40MHz, using a circuit better suited for high frequencies.

Thanks,
- Win

It won't work, because the heat transfer rate from the little TO220 tab
into the bulk of the oil is far too low.

Do you remember Cam Searle at MIT? He would walk into the lecture and
pull a ball of circuitry from his coat pocket.

He would flatten it out and show everyone it was a 3 transistor amplifier
with feedback, built directly over the schematic.

I forget the gain, perhaps 30 dB or so. The amazing thing it was flat to
100 MHz!

This was in 1968. Transistors were not very good in those days:)

Well, I'm actually doing *both* in an attempt to get back up to speed
again following a 2-decade lapse where I went on to study the
peculiarities of the universe(s) we inhabit. Things have moved on
quite a bit in 20 years. For example, the other day I ordered - for
experimental purposes along with a bunch of other stuff - an RF
amplifier driver IC from a well known supplier. I'd expected something
to come back about the size of the good old 555 timer, but the
static-proof bag labeled appropriately for this device turned out to
be empty - or so I thought. I was about to phone the supplier to
report the short-order, but thought I'd better double check just in
case. Anyway, I could feel *something* in the bag and eventually out
popped a fragment of plastic about 3mm square. But it just looked like
a corner cut off a wrapper and no way resembled an IC. However, a
friend of mine with better close-up vision was able to see there was
something resembling a tiny insect inside it. I placed it under one of
my microscopes and was astonished to see a minute IC within this tiny
chip of protective plastic wrapping. However, there was no way I could
get it out of this wrapper with my big, clumsy fingers, plus the
finest tip on my soldering iron would have bridged across all 6 pins
on one side of it, anyway. It didn't matter much, though, because on
trying to remove it from the 'scope, I dropped it somewhere on the
carpet and despite a lengthy search, was unable ever to find it again!
Thank God it only cost $5! But what on earth is the point of making
things so tiny that people like myself can barely see them, let alone
make practical use of them? In a few more years, event the most
dexterous of us are going to be stuffed if things carry on the way
they're going.

An amplifier input has stray capacity to ground that forms a RC network with the source resistance. This rolls off the high frequency response.

If the input stage inverts, as in common-emitter amplifiers, the capacitance from base to collector is magnified by the stage gain and appears in series with the source resistance. This is called Miller effect, and can cause severe rolloff.

If you mean that "fed back...to the tx" simply means that it goes to
the antenna (or the antenna changeover relay), and not into some
active stage in the tx, then yes...a qualified yes anyway. To get
you thinking more about it, what could go wrong with this scheme?
What sort of isolation is needed between the amplifier's output and
its input? What sort of "wire" should you use in the cable to get
this isolation? What should you do on the tx end to ensure that the
isolation is maintained? If the tx has amplifier stages, should you
be careful about isolation from the linear's output to the inputs of
those stages? Just _how_ does shielding work, and what will screw up
shielding that you thought was good? Is there perhaps a better
alternative to routing the amplified signal back to the unit where the
input was generated? ... There are probably some other questions
that are worthwhile here, too.

Cheers,
Tom

What are the design parametes of the transmitter's output stage?? If it is designed to function at 2 watt max and you apply 10 times that amount of signal to what may happen?/ The linear amp is designed be connected to the antenae with the input from the transmitter as it exciter signal generator.

I am afraid that as long as the machine sees them then it's OK. If we are all stuffed and have to buy new when something breaks then so much the better would be the manufacturer's take on things.

That said you would be amazed at just how small a thing you can hand solder with practice and the right technique. Just don't erect a mental barrier to the concept. I have never regarded my eyesight as being very good but I hand solder the smallest SMD's every day now as a matter of course at work including ultra high density QFP chips.

Just use loads of light and a magnifier for reference. Don't use a magnifying lens to look through for the whole job - bad eyestrain and headaches - just for positioning the component and checking the job from time to time. Binocular magnifiers of the type used by jewellers can be useful since they have two separate lenses they give less eyestrain.

Alec Wood M1BNK
Teesside UK

BTW I find the wife's feet to be the most efficient device for locating IC's hidden in carpet. Just make sure she's not wearing tights - they don't like static

Hey you two wags, transistors _were_ pretty good by that time!

For example, the 2n2222 suggested in this thread as an improvement
over the BC337 had already been available for what, 5 years?
(One of my friends was involved in its design.) And many other
better transistors were available for RF designs. For example,
remember the 2n918, 1300MHz typ at 4mA - 10V, and 1.25pF at 10V?
I used the 2n918 in 1965 and it was an old part then, IIRC.

I'm sure we can come up with a design matching Dr Searle's circuit
using parts from that era. Let's see, three transistors, 30dB and
100MHz? Hmm, probably a enhanced variant on a shunt-series pair...

Thanks,
- Win

Have you got the correct number?

The Motorola MRF233 is a 12.5v 15w device while the TP9383 is 28v and
150w!

guys,

I read somewhere it was preferable, if you are to use transformers from microwave ovens (high voltage portion) to remove
some "core" responsible for "sort of" regulating the output voltage regardless of the load. I also read there was an article somewhere talking about from a magazine called "amateur radio" and in particular in the 1998 may issue.

Does anyone know where to find this article? If I am not clear or missing something, please email me directly.

Regards,

Matt - G/F1ILU

I rather assumed that Mike was referring to very high values of 'very
good'. In consumer products, of course, we didn't see anything too
exotic, But I still have a stock of glob-top BC116A, which is something
like a BC 337 but PNP. And of course we had BC107/8/9 - even gain-
grouped ones. I used to charge my lads five virtual shillings if they
wanted to specify a BC109C. Then there were BF194 and 195 for r.f./i.f.
- horrible 'pluggable' encapsulations. But we had FM tuners with RCA
dual-gate FETS.

Hi, the resistors are far too high in value, try these. rc 390, re 100, rb-10v 10k, rb-0v 2.2k.

Hello all ...

I built the SMK that NorCal offered and found that the "larger" SMCs offered a less hassled building experience. I taped down the board , used an eye loupe, a coathanger holddown jig and with forearms resting on the table actually put the thing together and it did work ...much to my amazement. The board did not have to be lifted turned and snipped which was a real plus ...recognized this after building the K2 and tuner. It can be done and be an enjoyment at the same time.

This brings back memories. Of course you are right. The 2N918 was a
pretty hot transistor.

I was kind of hoping you would say that. I'd like to see what a PRB941
could do, and figure out how to get a healthy signal into 50 ohms without
burning up.

IIRC, the feedback resistor required a small cap in parallel for
compensation. This might get tricky at the higher bandwidths.

Those little blocks of laminations between primary and secondary do
not regulate the voltage. In fact, they make the output voltage more
variable inversely dependent on load current, and are approximately
equivalent to putting an inductor in series with the primary. They
provide a current limit function that is necessary with the negative
resistance characteristic of the magnetron oscillator. If you want to
reuse the primary and wind a low turn count secondary to make a
welder, the shunts are helpful to keep from blowing fuses and burning
windings when the rod sticks.

<pb@notthisbit.osiris1.co.uk> wrote:

Yes, I hate to think what it's going to be like in 20-30 years time.

But anyway, I have been using SMD devices for about 25years now, on and off, and can offer the following suggestions. This should get you into success with SMD for not much cost, other than your time.

Just start practicing with some old boards, taking a few SMDs on and off. You should be able to get plenty of old boards for free.

I painted my workbench top a light color, so you can see the parts more easily. I also added an alloy strip around the edge about 1/8 inch high. This stops them slipping over the edge onto the floor to vanish into the SMD black hole forever, as you found out.

I made a PCB mounting platform with a sheet of 5x5 inch alloy on a 4 inch "Lazy Susan" bearing (Doh, just realised the PC police will want to castrate me for that Susan bit, so must rush to finish!) The PCB is held on it with a few blobs of "Bluetak" or the like. You can then spin the board around so as to always get the best angle for the soldering iron.

You need a lot of light, a good background light, and, a high-intensity halogen spot on the work.

I work under a large 3 x magnifying glass, but it takes a bit of getting used to, and it usefulness depends on your vision. Another 10 x lens is useful to check joints.

You will need a good temp controlled 25 watt iron with 2-3 small tips, both conical and chisel. A couple of tweezers are essential, I find the ones with long curved tips are the best. I have also coated one pair of tweezer tips with a thin film of RTV, this stops the device from popping out of the tweezers, to vanish forever . Circular components are the most prone to this. Thin solder is also important, I use 15, 20 and 25 thou as required.

Philips, Siemens and probably others have published small booklets containing photographs of good and bad solder joints, and other common SMD faults. These are well worth getting hold of for a bit of study.

Above all, practice practice, then practice some more. You will soon find it's very easy. No leads to clip, no holes to drill.

Best of Luck,
Barry Lennox

Example of Murphy's Law. Important data is unusual, special or counter-
intuitive, so the catalogue compilers regard it as 'additional' or
'subsidiary', in error, and thus use 3-point type.

Many thanks, Ian. Useful tidbits of info like this help me build a
fuller picture of what gives. I knew there was a relationship between
gain and Ic, but not between Ic and Ft. The workings of the BJT at RF
are actually quite complex, it appears. Aren't audio amp designers
lucky?

Hi Paul:

You should also look at the behaviour of Ft with collector current. At
very
low currents it is inversely proportional to Ic, over some middle
range it is
relatively constant, and at higher currents it falls off again. The
transitions
between these regions vary a lot depending on device geometry and
doping.

The small packages also have better parasitics. The down side is
handling them and thermal effects.

Have a look at the Wainwright Mini-Mount stuff. These are self
adhesive
PCB's with most of the common SM footprints, controlled impedance
tracks and the like. Very useful for breadboarding.

Just buy a pair of micromanipulators from the same place you get
your microscopes. Speaking of which, I love my AO Series 11
Research Trinocular. _Must_ fit a video camera on it.

Look into the microscope, and there's your steady hand. Or if you want it in engineering terms, our natural hand-eye-brain-hand feedback automatically takes advantage of the extra loop gain from the microscope.

Matt:

If you have uses in mind besides a welder, you will probably want to remove the shunts. There are a number of on-line references, including: http://www.geocities.com/the_loaded_dog/ham/projects/vk4ye/vk4ye10.html

Considerable force is needed to remove them and you must be careful to avoid damage to the windings. You will almost certainly have to remove the low voltage filament winding (usually a few turns of red or orange insulated wire). You will see the 2 shunts (small stacks of laminated core material) between the HV and primary windings. Then support the core laminations on some substantial material that will keep the windings away from any other objects while you gently (or forcefully) punch out the laminations using a hammer and other suitable tools.

I have found that on some transformers you have to push the two shunts out from opposite sides, and on some transformers they come out from the same side.

Good luck,

Roger K6XQ

How so? The sheer number of pins? The inability to run traces between 0.5mm pitch pins? I don't see much difference, but then I used to be pretty damn good at laying out single-sided PCBs and that, like riding a bicycle, never really leaves you.

Best regards,

Ah well, you should have told us you collect microscopes! I now use a
stereo zoom microscope, and it is very useful, although I still do
most assembly under a 4.5 inch diameter 3 x lens. I did however, make
a batch of ultra-micro animal tracking beacons under the microscope.
As another poster pointed out, the eye-microscope-brain-hand feedback
loop sorts it all out for you without even thinking about it. Even at
the max 20 x I have no problems with unsteady hands, although about
10 x is more use.

>Well, I could have certainly used your wife and her sensitive feet

>cleaner. :-(

Every week or two, I put a piece of silk over the end of the vacuum
nozzle and do a "workshop sweep" in the places where the dropped SMDs
tend to gather. I usually get a few, plus some other useful thingies.
Of course, sorting them out often takes more time than it's worth.

From: David Vest <k8dv@fuse.net>
Message-ID: <v299cmshk5ce35@corp.supernews.com>
Source record: 38588

Just finished building up John Hanson's W2FS's 706 Remote Base controller from
article in May 1998 QST using a Basic Stamp 2 as the processor.

Wondering if anyone else has built one of these and what kind of problems did you run
into. I cannot get mine to respond to anything except the initial password and trigger the
link PTT. I have made changes to the program and reloaded the BS/2 several times, but
have had no success.

Looking for any ideas, I have also tried loading John's original code into the BS/2 with no
changes and still have same results. The code can be found on the ARRL BBS ftp file site.

Any help or ideas please email me direct.

Thanks
Dave K8DV

And on the one transformer I checked, the primary didn't have enough turns and
therefore drew too much unloaded current for my use.

If I was to do that again I would use two transformers with the primary in
series
and the secondary in parallel. That would , of course, give only 1/2 of the
rated
voltage you would get with one transformer.

Dear Spehro:

Naturally a fine-pitch device requires more space
around it for vias, etc. and therefore, if component
density stays the same while the number of component
leads rises (due to finer pitch parts...), the area
for interconnect must contain more tracks, and the
routing becomes much more difficult and time-consuming...

As pitches get finer, engineers do not seem to
realize that YES, you can fit more parts on a board,
but you can't just do that without concerning yourself
about how the heck it's going to be interconnected !!

All the best, Jean

Op-amps can be used to amplify DC voltage depending on the voltage you want
to amplify and what amplitude you want to amplify it too. Check out op-amp
mfg's such as motorola, maximm, analog devices. They have application notes.
The same circuit can be used to filter out any AC voltage that may be
present.

Yes, I think the cross-posting has caused overly complicated answers.
Obviously, DC amplification is pretty common. A lot of the suggestions
have been in the realm of the esoteric, when I'm not sure the
question is at that level. DC offset is easy to remove, you just
null it out with a similar voltage of an opposing polarity. Of
course, at finicky levels, the issue isn't so much the DC offset,
but that temperature instability will make it difficult to
keep that null constant.

As with many questions, the answer follows the application. It
may not require anything more than an op-amp, or it might require
some of the solutions that have been in this thread already.

Thank you for your hints!

This may be a non-critical design, but there are so many things that can go wrong that experimentally fishing for just two concurrent bugs may take forever...

Frank:
>> In fact a combination of a High Pass - and a Low Pass
This was my thinking too.
Have you ever seen this done in practice?

Pete:
>> put some sort of resistive termination at the antenna end of the filter
I had been wondering abt that.
Rule of thumb, I'd put a resistive load (signal to ground) at least 2-4 times the (supposed) impedance. Does it sound abt. right? Is it needed, in view of the presence of wideband transformers?

Reg:
>> download programs
Thank you, will do!

All:

Do you agree that 800 ohm is a decent ballpark approximation of a short whip impedance?

I should read up A LOT to be able to model it, but I know that Palomar Engineers uses an 800-to-50 ohm matching transformer in its passive whip-to-coax matching device.

Also: I have been looking for a commercial device of this kind. Various shops told me they might have liked a supplier coming up with a small, mag-mount, HF-optimized, 50 ohm out device for in-car listening, and that none was available.

I even talked to makers of active car antennas, who said that making one was no sweat from a manufacturing standpoint. They only would remove the FM BC amp channel and raise the cutoff freq of the AM BC one - cept they would not even consider damping MF.

The tiny market would not even warrant the effort of optimising the choice of a few SMD components onm a production run, esp. since they would have to SELL the contraptions into a market they don't even know.

Do you think any sizable number of hams and SWLs might want to buy a good, clean source of HF spectrum for their cars?

=======
I found some practical designs in ARRL Handbook . In 1995 Handbook ref pages
16.15-16-17
Low + highpass sections to be segregated by adequate screening
Home brew filter enclosures can be readily made from fibre glass double
sided PCB.
Final testing and adjustment preferably with aid of spectrum analyser with
tracking generator.

I'd say place the wires apart using aluminum foil if possible. Using
RF anything is likely. 40MHz is not really that high.

408. Lavoie LA 800, Simpson meter ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-17 04:55:37 UTC
From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <v2f36pghdr3d6a@corp.supernews.com>
Source record: 38511

I'm restoring an old Lavoie LA-800 WWV Comparator and the Simpson AVC meter is beyond repair. Simpson plated the magnet with some kind of chrome and its peeling resluting in little pieces lodging between the poles and armature. The meter is for a 2 3/16" round hole but has a square face plate. The meter face is 0 to 15 VDC and on the side in small print is SK 525-18. I don't know the sensitivity of the movement but it connects to the AVC line thru a 560k ohm resistor. I'd sure like to find a replacement, any tips appreciated.
tnx

Not to my recollection. The Eddystone 898 dials (that number just came out as I typed... how... or why... did I ever remember that?) were sold on their own with a template for marking-out. However, other suppliers did sell some ready-made metalwork for published projects involving the 898.

>Like a fool, I ditched one a couple of years ago and have been
>regretting it ever since :(
>
After about 30 years, I let a very dirty example go at a flea market. The collectors fell upon it like vultures!

For real bravado, a friend once sawed an 898 dial up to convert it into a short slide-rule scale, like the Heath SB300 series which were 'the current look' at the time. With smaller dial-cord pulleys (and after 6 months work to make the 0-500 logging scale read direct in kilocycles... well, roughly, kind of...) it worked just fine - even won RSGB's construction prize!

Just bought a UHF GP2000 front panel programmable...sweet
little radio I might add. Anyway, got 2 features I can't figure out.
How to get the display to show chan tag, and how to acess the other 2
scanlists. I know the obvious anwser is to call motorola, but my local
dealer is a real butthole. I know someone else out there has one of
these radios with the same qusetions. Let me know

Hi!
I was wondering if I could tap the collective wisdom for a little help assembling a CI-V interface. I ordered the board from FAR Curcuits and I guess I was a little naive. At the hamfests that I've been to they've had these nice little baggies with the board, a schematic, and a parts list. Well, this time I've got a board and nothing else. It mentions figure 22.80 out of the 2000 ARRL Handbook. So I went searching and can't find that on line.
I did find a schematic, but it doesn't match the traces on the board. So, I was wondering if anyone would mind scanning the relavent pages so that I can get this darned thing put together. :) I'm heading out to the used book stores to look for a copy myself, and if that doesn't pan out I'm going to try to order one. I just hope they haven't changed anything since then...

Thanks in advance!
Pat, K0OOK

It's in my 2001 Handbook on page 22.45. There's a PCB template and layout on
page 30.62. I don't have a scanner, but I often
use my digital camera as a scanner, and can email the images.

The stuck meter measures 1840 ohms on my Fluke 87...
I put the Fluke in series and read about 3 micro amps..
Using the Fluke as a voltmeter I saw about 2 volts..
The meter is very similar in appearnce and size to the S meter used in
Collins S-lines.

My RS-12A power supply died after a lightening strike in Summer 2001.
It's been on the shelf since but I am considering repairing it.

Symptons are: when power is applied, the power light comes on and I
hear the hum of the transformer, but there is no dc on the terminals.
Should I start by replacing the two transitors (2N3771)?

I would appreciate help/advice from anyone on how to trouble shoot
this.

Thanks in advance,

Woods

Hi,if you only want to remove DC ,why not try a cap?You can connect it at your amplifier`s output in seria.

Excellent resource! Thanks Chuck.

You probably want to disconnect the output leads of the transformer and check the transformer. If it
is good AC output, then it is probably economical to repair.

Steve

Woods:

Power supplies like yours are pretty easy to repair, but the best way is not to randomly replace parts. There are many possible problems and you need to approach the troubleshooting in an organized way, eliminating what is working and moving on to what isn't. You will need a volt/ohmmeter for this work.

Here is a link to a schematic that works:
http://www.repeater-builder.com/rbtip/rs12a.html

As a previous poster suggested, check to see if you have AC coming out of the transformer. If you don't, check the fuse and switch on the primary side. If they are good and you still have no AC out of the transformer, and all the wiring seems OK and you have 117 volts AC going in the primary, then the transformer may have an open secondary winding. This is unlikely, but you should check to be sure. If the transformer is bad, you need to decide how badly you want to repair the supply, as that is the most expensive part.

If you have AC coming out of the transformer, then check to see if you have DC on the filter cap(s). It should be in the 16 - 22 volt range on the 17,000 mfd cap and even higher on the 1000 mfd cap. If you don't find these two voltages, you probably have blown diodes. Check all 4 of them with an ohmeter..two are separate and two are molded in a single module. If bad they will either read as open or shorted with the ohmmeter leads on either way. If good, they will conduct one way but not the other. They are relatively inexpensive to replace if they are bad.

If the diodes are good and you have DC on your filter caps, then your regulator chip, driver or output transistor(s) are bad. You can check the transistors with your ohmmeter, like the diodes, looking for opens or shorts. It is a little more complicated and can be confusing because of the extra terminals. The chip isn't as easy to test so if you have satisfied yourself that tall the other parts are OK, then try subsitituing a chip. The 723 regulator chip is very common and you should have no trouble finding one to use.

If I had to make a guess, I would bet the regulator chip is bad. It is the most fragile part and is easy to destroy (don't ask me how I know this).

Good luck,

Roger K6XQ

==========
Suggest you take it step by step.
First apply power (presumably 117 V) and check AC output of secondary (Low Voltage) transformer winding .
With the winding output (if OK) probably between 18 and 24 V, load the winding with 2 car head light bulbs in series and check voltage on this load . If voltage is hardly any lower than without load , then transformer is OK.
Now check output rectifier module or discrete diodes DC voltage . If between 20 - 30 V these are OK
Now you can start checking components on the regulator circuit board ie transistors , perhaps an opamp or voltage control IC or perhaps a separate zener diode and the passive components .
Does the unit have a 'crowbar' over voltage trip circuit with a thyristor and an associated fuse ? If there is a DC fuse ,is it OK or blown ?

Following a lightning strike ,if there is no visible damage ,semiconductors (ICs) are the most likely victims.

Good Luck

Frank gm0csz.kn6wh@ntlworld.com

I had a similar failure in an RS-12A and it turned out that the voltage was going high enough to trip the built in crowbar circuit.

And, as another poster suggested, it did turn out the be the LM723 voltage regulator IC.

For my troubleshooting, I removed the wire going the the SCR and that disabled the crowbar. After doing that, the rest was easy to fix.

As is the case with all lightening strike cases, even apparently "good" components should be replaced if they are not too numerous/expensive. I used to service TV sets and it seems that the lightening strike cases always had multiple problems. You'd fix one problem, and it would be back a few weeks later with another. You'd fix that, and then back again. It became impractical to continue the repairs.

It's for broadcast TV, bands I, III, IV and V. I'm pretty sure when I say than the bandwidth at 10.7 MHz is of the order of a couple of megs, OK for mono pictures?

Icom sell a TV adapter than takes its feed from the 10.7 tap but it's a)discontinued, which means b)they're like gold dust, and priced accordingly.

One hair-brained scheme I had in mind was to mix the 10.7 with a UHF oscillator (from the guts of a TV modulator?) and let a normal TV do the demod.

In many applications the type of capacitor is not too important. For a tube testor about all they will be used for is to filter the power supply. As long as the voltage rating is the same or somewhat greater and the capacitance is the same (you may use more in a power supply filter) you should not have any problems. It is just unusual to find large values of capacitors that are not polarized.

I have one of these I picked up at a hamfest for $15. Same symptoms. I went to RadShack and got a new 723 (less than $1) and popped it in, no problems since. Replace the 723 first, they are cheap and common, and a more cost-effective first step than actual troubleshooting.

I went through this back in the errly 90's with a small hospital, they had lightning strike the main AC feed into the building. Instead of leaving the X-ray system as dead and calling their insurance company. They had the X-ray system fixed, the insurance company would have replaced the X-ray system if they hadn't had it repaired. But as they had it repaired, the insurance company would only pay for the inital repair. After about 3years, and many service calls they finally sprung for a new system.

Woods -

Here is a popular article on repairing the Astrons that took a lightning hit
and
hombrewing your own - good theory on how it all works with the 723 regulator
IC

David Metz, WA0AUQ
Regulated Power Supply construction
(or what's Inside your Astron)

http://www.seits.org/features/pwrsup.htm

Schematic for this design
http://www.seits.org/features/pwrsup.gif

This and the Astron schematic and you are off to fixing your unit.
BTW, I have an RS-12 on the bench right now --
another cheap acquisition - 723 first item replaced !

There are a large number of CI-V interfaces using everything from
transistors to MAX 232 ICs.

First, here is the original Icom CI-V schematic:
http://www.plicht.de/ekki/civ/civ-sch2.html

Here are a few other approaches !

http://www.plicht.de/ekki/civ/civ-p2.html

http://www.g3vgr.co.uk/civ.htm

http://www.qsl.net/ok2wy/projects.htm

Here is the original schematic from the September 1992 QST project
(FAR circuits has a board for this one as well)
http://www.qsl.net/civ_commander/interface.jpg

Mike, let's not drop this subject. We'll use a new title for the rest
of this thread, Prof Searle's 100MHz 30dB 1968-era 3-trannie amplifier

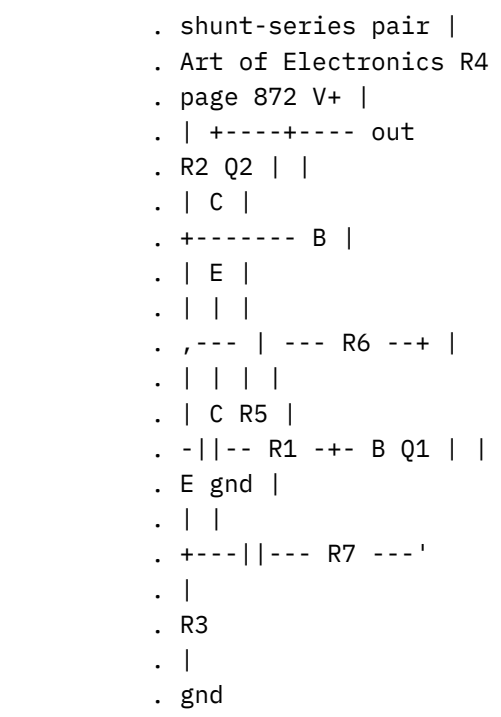
OK, I'll start by posting a simple back-of-the-envelope design. The
drawing below is taken from our book, figure 13.13, where we describe

the operating principle of the amplifier. It has two local emitter-degeneration-feedback gain stages (R2/R3 and R4/R5), plus two more nested two-transistor feedback loops (R6/R1 and R7/R3). Clever, huh?



I first learned of this configuration in the late 60s, it was popular in some circles. Mike, does this look familiar?

Of course it has only two transistors, but with simple calculations using 2n918 parts, I fell just a bit short of the specs. There are several good ways to add a third transistor to the shunt-series pair to enhance its performance. Which is best depends on the answer to an important question, "What's the source impedance, and what's the load?" I'd prefer a low-capacitance scope probe for the latter. :>)

Give it a quick lookover and we'll pick up the thread again.

Thanks,
- Win

443. Re: Astron RS-12A Repair Help

Newsgroup: rec.radio.amateur.homebrew

I had (2) 20 amp Astrons go south on me in a week. Both were the result of a "brown out" due to lights flickering from either a storm or power line problem. Nothing else, not even my "unprotected" computer (which was on at the moment) took a hit. In both cases, it was the Bridge Rectifiers at fault.

Not so hairbrained at all Martin. It's probably the simplest, quickest and cheapest way of doing it. This link is for a converter for the AR5000, but should work well with your R8500.
http://www.aoruk.com/pdf/5000tv.pdf
Note that your ICOM may superimpose 10-15 volts on the IF output - My ICOM R7000 does. I cannot say what bandwidth your R8500 has at 10.7MHz but my ICOM R7000 bandwidth is around 5-6MHz so you should be able to receive the sound and colour carriers as well.

Also, check this link for other article relating to TV via your radio.
http://www.geocities.com/toddemslie/vhf_dx_articles.html
It includes a couple of articles on filtering as applied to ICOM scanners/receivers, as well as a wealth of info on DX TV reception.

If you need any further info, please feel free to email me.

Steve

Martin,

If you have an IF which is a couple of MHz wide then you should be
able to get Monochrome Video through, it's going to be a bit blurry
for 525 or 625 lines.

I like the idea of mixing it back up to a regular TV frequency - use
as low a TV channel as possible.

If you want to cook it yourself solution look at the MC1330
synchronous demodulator. Old, Simple and Cheap - just like me :)

Golly, that sure looks familiar. I can't say for sure as it was such a long time ago, but let's go with it.

As I recall, the input was driven from the 50 ohm source impedance of a network analyzer. I'm not sure, but I think the output drove 50 ohms directly. That might account for the third transistor used as an emitter follower, but I rather see what else you had in mind.

The compensation cap went across R7.

Should there be a bypass cap from the emitter of Q2 to ground? R5 is going to be quite large due to the stacked voltages, which would make R4 really large to obtain much gain. Bandwidth would suffer, and the feedback resistor R7 would start to dominate.

Mike

Yes a good possibility, although no voltage gain results.

> The compensation cap went across R7.
```

Hmm. Normally there isn't enough loop gain in the shunt-series pair beasts I've designed to need such a trick.

> Should there be a bypass cap from the emitter of Q2 to ground? R5 is
> going to be quite large due to the stacked voltages, which would make

Yes, exactly right. Ideally one would share the gain task between the two transistors, but I wasn't able to get the 2nd stage gain up to snuff and a bypass (with a series resistor?) could well solve that. Ah, with no degenerating series resistor for the bypass cap, perhaps a cap across R7 might be needed after all, to add a fortuitous zero in the loop.

Thanks,
- Win

This may have been due to the layout. There was no attempt to shorten the
leads. Instead, the circuit was wired directly over the schematic, and I
was astonished to see it work, especially at 100MHz.

I tossed this in SPICE using three MMBR941's, the last one as an emitter
follower. After fiddling a bit with the bias, here's my results:

Parameter 1KHz 200MHz

Open Loop Gain 46.14 dB 37.3 dB
Closed Loop Gain 30.50 dB 29.99 dB

Maximum Output 9.11V p-p

No compensation cap was needed, but it definitely needed the 100uF from Q2 emitter to ground.

Now I'd like to see how it really should be done!

Mike

Actually it gets better not worse. Remember Bob Pease and his classic
rat's nest lashups to test some IC-designs on the bench? It keeps the
capacitance down and I imagine low inductance is a possibility with some
effort at places you really need it.

Hmm, pretty nice! That was with a 50-ohm load, right? Did you find
the -3dB down point? Also, what supply voltage did you use, are you
sure each part's Pd was reasonable?

Hmm, did On Semiconductor pick up or continue the '941 after Motorola?
I see APT and Microsemi 2nd-source the part. Philips has the PBR941.

But Mike, the MMBR941 wasn't available in 1968 was it? When did it
come out? I mean, I don't remember any jelly-bean 8GHz transistors
that far back, and having only 0.3pF of capacitance is a big help!

Let's see what we can accomplish with a true vintage component, like
the 2n918, or better if it was available.

> Now I'd like to see how it really should be done!

Nah, your circuit the looks like the winner. But I'll show you my
2n918 circuit if you show me yours. :>)

Thanks,
- Win

Actually, you are right. I always get parasitic oscillations with fast transistors and long leads, but I guess a couple of nanohenries really isn't going to be a problem up to 100MHz. The reactance is so low compared to the rest of the circuit it won't do much. But I was horrified when I first saw it. This ain't gonna work. But it worked fine.

The parts were cooking. No load, but I set the bias for max swing just to find the range. Vcc is +15V. The -3dB point is 558MHz.

> Hmm, did On Semiconductor pick up or continue the '941 after Motorola?

I haven't been able to find anything at ONSemi. MaCom supposedly picked up the line but I haven't been able to figure out how to navigate their web site to find out.

> I see APT and Microsemi 2nd-source the part. Philips has the PBR941.

For some strange reason, they offer the PBR957 as the replacement for the MMBR941 instead of the PBR941. They also have some nice high frequency ones in the BFG series. Here's a short list:

P/N GHz
BFG403 17.0
BFG410 22.0
BFG425 25.0
BFG480 21.0

These have a VCEO of 4.5V. I don't know what the base-emitter breakdown is, but it can't be more than the MMBR941 at -1.5V. So power on/off transients could be a problem if there's large caps in the circuit. It may not hurt the device, but I understand all it takes is one event to degrade the noise figure.

> But Mike, the MMBR941 wasn't available in 1968 was it? When did it
> come out? I mean, I don't remember any jelly-bean 8GHz transistors
> that far back, and having only 0.3pF of capacitance is a big help!

True, but the 2N2222 didn't do very well, and I happened to have the model for the MMBR941 already loaded and wanted to see what it could do. In real life, there would be three parasitic oscillations all running happily:)

> Let's see what we can accomplish with a true vintage component, like
> the 2n918, or better if it was available.

Yes, that's a much more difficult task.

> > Now I'd like to see how it really should be done!

LOL! I'll upload it tommorow and let you shoot holes in it. But I really want to find out how you can get away without using a bypass cap.

=========
Since the discussion is on Astron Power Supply Units , may I bring up
another subject regarding these units

I have a RS-50A unit , 13.8 V -50Amperes max ., Astron serial nr 8804024.
Although provided with a Yaesu sticker and bought in the UK ,the unit is
made in the USA ,hence it is highly likely that the transformer is
designed for 234V- 60Hz. Here in Europe (incl.Scotland) the AC freq is 50
Hz. and we have fused power lead plugs .
For the Astron unit I fitted a 13 Amp fuse .

I have 2 problems with the unit :
1) When switched on after having been idle for some time the mains circuit
breaker trips due to the high inrush current ,but the 13 Amperes fuse
survives and so does the 10 Amperes fuse ,fitted on the unit.
Cure : I'll fit a 50 Ohms -50 Watts resistor with integral heatsink in
series with the primary transformer winding. As soon as the DC output
voltage is present (with a few seconds time delay) the contact of a DC coil
relay shorts the resistor providing the transformer with the full (nominal)
230 V - 50 Hz AC supply .

2) When switched on the transformer being located close to the metal cabinet
acts as a loud 'hum producing transducer'
I am sure this problem would not exist had the the transformer be a torodial
type.
I now intend putting the PSU in a wooden enclosure ,but before doing that I
would appreciate any feedback regarding the use of the RS-50A in the USA
or other countries with a 60 Hz power supply system.

TIA for any response

I've always heard them referred to as chopper stabilized or commutationg
autozero (CAZ for short) amplifiers. There are also some very good amps
out there made by Burr Brown, Intersil, etc which may be applicable. As
much as I hate to advocate it, you can also manually trim each of the
stages with a pot. Many amps even have pins specifically made for this.
You may get stuck using a plus and minus supply also.

The power supply transformer will be slightly more efficient at 60 HZ and
the filter capacitors will eliminate somewhat more ripple in the supply.
Overall it should work beter.

The fuse conducts when checked with the ohmmeter. Voltage going into the transformer is ~120V AC. Voltage across the two wires coming from the secondary (blue and yellow) into the bridge rectifier (BR) is ~38V AC. Voltage across the other side of the BR (yellow and red wires) is ~18V AC. Voltage feeding onto the cirucit board from the BR is 18V. I actually get a reading both AC and DC there. The 16000 and 1000 mfd filter caps have 25 and 32 V DC, respectively. Voltage on the transistors is ~14V DC.

D1 and D2 conduct in one direction but show reflectance in the other. D3 and D4 conduct in both directions (hmmm). Voltage across the D1 and D2 is 32V DC. Voltage across D3 and D4 is nil (even on the most sensitive scale). Does this identify the diodes D3 and D4 as defective? I suppose the LM723 chip could also be defective. How do I determine the correct replacements for D3 and D4, should these be the problem- from the schematic?

Thanks for all the helpful posts and email responses.

That was a nice design, Jim, something to be proud of. I remember using it way back when. But it has four transistors in the active signal path, rather than three, and goes to 40 or 50MHz with a gain of 34dB into a 1k load, rather than 100MHz into ? 50 ohms. Hmm, it appears Prof Searle's design was no slouch. :>)

OK, that's a shunt-series pair, as I posted, but you call it "Prof Searle's 100MHz 30dB 1968-era amplifier." My question is, did you simply use my thread title, or do you remember, was Prof Searle's design a shunt-series pair, or possibly was it something else? For example, Jim Thompson's design isn't a shunt-series pair, yet sports a certain simplicity.

```
. Mike Monett's mods, V+ V+ = 15V
. shunt-series pair | | G = 30.5dB (no load)
. (Art of Electronics R4 | -3dB BW = 560MHz
. page 872) V+ | C Q3
. | +----B all MMBR941
. R2 Q2 | E
. | C | 8.9V
. +------- B +---------- out
. | E |
. | | 5V | R1 = 50 (or ext source)
. ,--- | --- R6 --+--, | R2 = 750
. | | | | | R3 = 100
. | C R5 === | R4 = 470
. -||-- R1 -+- B Q1 | | | R5 = 470
. | E ground | R6 = 10k
. R9 | | R7 = 3.9k
. | +---||--- R7 -----+ R8 = 470
. gnd | | R9 = 15k
. R3 R8 bypass R5
. | |
. gnd gnd
```

WRT your version, I see you've added R9 to bias Q2's emitter up at 5V. Is there a reason for that (e.g., higher Q1 Vce), or was it to reduce R2, thereby extending the R2-Cob Miller integrator bandwidth of the 2nd stage, etc.?

Another comment, with R1 = 50 ohms (i.e. the RF generator's impedance) and R6 = 10k, the first R6/R1 feedback loop of a usual shunt-series pair is basically wide open, increasing the open-loop gain available for the second R7/R3 feedback

loop. Hmm, I wonder, is this a good idea, or a bad idea?

BTW, in a real design I'd scale back R6 and R9, to reduce the uncertain effect of Q1's beta. Usually high-bandwidth transistors have very poor DC gain. In this case, 1.7V of Q2's 5V emitter voltage is from Q1's uncertain base current dropping across the 10k resistor. :>)

Thanks,
- Win

The fourth transistor is a follower, and the feedback loop from that
emitter is a *DC* loop. The AC loop is the same as Searle's; Searle's
DC loop is different... mine sets Vo = Vcc/2.

Searle's design uses discrete transistors, one of the hottest devices
available, fT = 8GHz (were MMBRC941's available in Searle's day? ...I
think not... there were 914's, but I don't remember 941's), mine uses
a very early I/C process with 25.4um x 48.1um emitters, fT = 750MHz
:-)

Searle's circuit uses 42mA, mine 12.5mA.

I haven't followed this thread until Mike's post... how does Searle's
circuit drive 50 ohms?

We don't know. It may have driven the 50 ohms of the network analyzer at low level, or he may have used a high-impedance probe. I don't remember for sure, but I think it went right into 50 ohms. I don't recall him wasting time with separate measurments of the probe bandwidth and having to calculate the overall gain. The demo went pretty fast, then it was time for the math.

Mike

> I first learned of this configuration in the late 60s, it was popular
> in some circles. Mike, does this look familiar?

One of the circles was broadcast audio. A lot of these were used in BBC
audio equipment, AIUI, with variations around R5/R6, e.g. R5 decoupled
or not, R5 split in two with R6 going to the join, or a resistor in
series with the decoupling capacitor. IIRC, if the capacitor in series
with R7 is a big one (as it would often have to be), settling time on
switch-on can be long, so the capacitor is omitted. It then becomes an
interesting exercise to *calculate* appropriate resistor values, without
the aid of SPICE, of course; that didn't exist in the late 60s.

A little exercise was set in an examination for service techs in UK at
the time or a bit later: given the component values, determine the d.c.
voltages at all electrodes and the gain! I saw what was alleged to be a
'model answer', in which the collector current of the first transistor
was apparently deduced by divine inspiration. The circuit was alleged to
be the input stage of a household tape recorder recording amplifier,
which seemed a bit unlikely since R1 was 680 ohms! I wonder how many of
the poor B***s failed through that piece of incompetence.

Win was concerned that I used Prof. Searle's name as a title for the html file, probably to avoid confusion like this. I used the title only to identify the thread, and we only suspect this configuration is the one he used. We don't know for sure.

The MMBR941's were not available in those days. They are in a SOT-23 package that didn't appear until later. I only used it since the 2N2222 didn't perform well, and I had the MMBR941 model already loaded so I didn't have to hunt for ones like the 2N2369 or 2N918.

Usually the MMBR series is a t0-18 or t0-92 converted to the SOT package, but the 2N941 appears to be a PNP according to an entry at

http://radvs.boom.ru/vtn2.html

If this entry is correct, the 2N941 was not the forerunner of the MMBR941 and could not have been used in this circuit.

The SPICE version shown on my web site is only an initial stab to get a feeling for the bias conditions. We have no idea of the actual supply voltage or current drain of Prof. Searle's circuit.

Mike

You were right - sorry for the confusion. I just used the thread
title, and have changed the html file to show the relation to this
thread in case anyone else joins the thread in the middle.

I don't know for sure if this is the design he used, but I strongly
suspect it. There was an instant flash of recognition as soon as you
posted it, then my mind starts playing tricks, the same as changing
your answer on a multiple-choice quiz.

My gut instinct is this is the one he used. I have a strong
impression the feedback went to the emitter, which limits the number
of configurations in a two-transistor design. I believe the output
went straight into 50 ohms, which accounts for the emitter follower.

But this is just speculation. I don't have a copy of the original
schematic.

> reduce R2, thereby extending the R2-Cob Miller integrator
> bandwidth of the 2nd stage, etc.?

I used the time-honored "tune for maximum smoke" to get a feeling for the voltage stackup. Maximum smoke means max output swing with both hands firmly planted on your seat.

I set the collector resistances low to drive the stray capacity (not shown) and Miller effect. The bias drove me crazy. I recalled that R1 just pointed left in your original diagram, and it was not connected to anything, so I added R9 to make a voltage divider. The values for R6/R9 are way too high, but it was getting late and I was running out of time to make the simple change and have to redo all the plots.

The problem with my procedure is R5 got quite large. This means a bypass cap is needed across R5. Your circuit didn't need one, so I really would like to see the more organized approach that you would use.

> Another comment, with R1 = 50 ohms (i.e. the RF generator's
> impedance) and R6 = 10k, the first R6/R1 feedback loop of a usual
> shunt-series pair is basically wide open, increasing the open-loop
> gain available for the second R7/R3 feedback loop. Hmm, I wonder,
> is this a good idea, or a bad idea?

It's definitely not a good idea to have such high resistance values for R6/R9. Lowering them would tend to fix Vb1 which stabilizes the voltage across R3.

I like to have a resistance in series with the source just to get an idea of the input impedance. I raise it during the analysis to see how much effect it has on the results. In this case, the feedback to the emitter boostraps the input impedance, so it is quite good.

> BTW, in a real design I'd scale back R6 and R9, to reduce the

> have very poor DC gain. In this case, 1.7V of Q2's 5V emitter
> voltage is from Q1's uncertain base current dropping across the
> 10k resistor. :>)

Yes, you are absolutely correct. It was just getting late.

> Thanks,
> - Win

Win, I'm sure there must be an optimum supply voltage where anything less would simply not give enough to bias the trannies on, and more would simply waste power as my approach did.

Can you show us your approach? I would like to sit back and be enlightened as always when you talk about how to design.

Mike

473. Need VHF/UHF antenna advice

We live in a condo which pretty eliminates any possible outside antenna ideas. I'm looking for some type of antenna that can be used indoors. I do have a window right next to my chosen area for a "station" that could be utilized in some fashion. I realize that the gain on an indoor setup isn't going to be the greatest but is there something I can buy/build that would work at 144/440?

I know these noob questions get old, but thanks in advance for any advice you can offer.

> :-)

Whoa, 8GHz transistors in 1968, that's pretty impressive. My 1983
Motorola databook lists up to 1.6 and 2.0GHz SOT-23 types under VHF
amplifiers, plus 4.0 and 5.5GHz types (MMBR930 at 30mA, 5V) under
RF SOT-23 Transistors, and that's the highest available for 1983.

> Searle's circuit uses 42mA, mine 12.5mA.

That's pretty detailed memory, do you know his circuit?
I'm simply speculating, not having ever seen it.

Thanks,
- Win

You should look into building a J-Pole. You can build one with 300 OHM
TV twinlead and hang it outside or inside a window.

What I call "Searle's circuit" is what Mike posted. The values are
from "Mike's" circuit. Looking through SEEC v5 (Thornton, Searle,
Pederson, Adler, & Angelo; 1965), I don't find that feedback-triple
configuration at all. (Thornton and Adler were my instructors at MIT;
Solomon did his thesis under Pederson at Berkeley, which is where I
think the configuration originated.)

About 4 feet behind me right now, sitting next to the window is a discone on a pvc stand, it hits the local repeaters just fine. Just be aware that you better work out how you are going to keep rf out of your power supply, mic cord, and radio with almost no seperation between antenna and rig. I only operate low power from this setup, since my apt complex manager has been very definite about no external antennas and I can't have anything showing to the outside. I do all my hf operating from the station in my car, since my complex has no rules about what I do with my car. At my previous apt where I could keep the discone on the porch outside, I was able to use it with an Icom 706mkII g and work 6m during field day.

Other experiments I have tried include a 9 element yagi for 440 hung from the ceiling with string, fixed in one direction, it did allow my handheld to hit a repeater that it couldn't hit with a duck. If you want both 2m and 70cm from the same antenna working omnidirectional, your choices a pretty well limited to a 2m 1/4 wave vertical, a dual band jpole like a copper cactus or a discone.
thanks, John.

A filter is always nice in that circumstance to remove alternator whine, if
any. I've found that the Radio Shack #270-051 works like a million bucks...

> at that point...

Since the output of the bridge is pulsed DC it will have both DC and AC
components.

If the capacitors are bad they will never charge up and even out the voltage
swings from the bridge.

It will appear to be AC at roughly half the input voltage on a cheap meter.

Is there an Oscope available to help check out the equipment? Or is the
repair being done with just a vom?
thanks, John.

It's a much better part than either of those transistors, and
possibly better than anything else available in 1968. BTW, do
you have any of them?

> ... If this entry is correct, the 2N941 was not the forerunner of
> the MMBR941 and could not have been used in this circuit.

That's correct, the 2n941 is a early transistor, no relation.

Thanks,
- Win

==========
Yes ,indeed . Perhaps a coincedence ,but in QST -Feb2003 , pages 38-39 there
is an article by WB6INQ on this very topic.
The 300 Ohm tv ribbon dual band J-Pole has been fitted inside a piece of
plastic pipe. Also is needed approx 25 inches of RG-174 coax cable and
obviously a SO-239 or even better ,female N-connector .

Not quite, in "Searle's" circuit and the 1552/53 the AC feedback is
emitter-to-emitter.

Go to www.elecdesign.com and check "Pease Porridge" for
6 January 2003. Therein Bob Pease (of National Semiconductor)
describes the George A. Philbrick K2-W general-purpose
operational amplifier. Just two 12AX7 dual triodes and two
neon bulbs acting as a "voltage-dropping zener." The K2-W was
made during 1951-1971 (20 years!) and cost $22. The first
"709" op-amp cost about $25 (general purpose specs). It was
in a neat little plug-in plastic "chassis" with an octal tube base,
the "top" flaring slightly to hold the two 12AX7s side-by-side.

Following the Electronic Design magazine schematic will let
you understand the quiescent DC voltage shifts that enable
DC level amplification. Problem is, you have to STUDY it
since it isn't intuitive.

For a more all-around example of DC-coupled amplifiers, look
at any old Tektronix 535 or 545 oscilloscope manual and one
of the plug-ins for either (both take the same kinds). Those
manuals have the full schematics with quiescent DC levels
and example AC waveforms given in each diagram fold-out.

For a much greater variety of examples, look at National
Semi, Fairchild, or Motorola databooks and observe that many
op-amps are given in representative schematic form on their
datasheets. Again, with some STUDY you can sit down and
check out quiescent DC current flow and voltage levels (easier
with bipolars due to reasonably-constant Vbe in base-emitter
forward conduction) versus the built-in resistances.

Jason, please phrase your questions as questions you've
already thought about instead of bringing up some "challenge"
condition such as the "high-pass filter" thing (not really
applicable to DC coupling in DC-AC amplifiers although it

does cause a high-frequency rolloff). DC amplification has been going on in electronics since before WW2, in tube and then in semiconductor circuitry.

The earliest file date I have on a cad file for a system that used
them is Oct 31, 1990. The datasheet was in a series of Motorola
databooks that were probably distributed one or two years earlier.

Sure, there are many to choose from now. I like the MMBR941 for
general-purpose use up to about 1GHz. They are a 2N2222 with wings:)

OK, I put mine up. Can we take a peek at yours? I'd like to see what supply voltage you used, and how you got rid of the bypass.

This circuit is deceptively simple. But due to the voltage stackup, you gotta have a plan, or you end up with problems like mine has. What's your plan, and how did you distribute the voltage between the two gain stages?

The other gotcha is you are restricted to a fairly narrow range of collector resistance to maintain bandwidth. But this leads to dissipation problems in the transistors.

Another problem is to meet design goals with 1960's era transistors. The 30dB gain figure was only a recollection. The statement "flat to 100MHz" dos not tell us where the -3dB point was. Perhaps with modern tools, we can get a fairly good idea of what it might be.

So the circuit is not as simple as it looks. I showed the wrong way to do it. What's the right way?

Amplifacation is a process where frequencies modulate or combine to produce a new charictoristic frequency at a higher or lower output, much like Plank's wave guide inwhich waves cancel or magnify when passing through a grid... The formulas canbe found in almost any tech manuscript, but the results are more often not "not quite what you expect". Check out my homepage at "http://www.aeons2c.com" for some exciting new news!

International Crystal in Oklahoma City, OK. Don't screw around, send
them the channel elements for recrystaling, calibration, and aging.
You get exactly what you pay for, and ICM is first rate.

Those are the same elements as used in Mitrek radios. You should
have little trouble finding them from ham swaps, or from International
Crystal.

If all else fails, contact me via E-mail. I may have some extras
that you could send to ICM for recrystaling.

FWIW: The MSR2000's a nice box. It should make you a fine repeater.

I agree that ICM is the place to send your elements to.

Check out www.batlabs.com however as they may have additional information.

507. Digital VFO mixer using flip-flop?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-22 01:20:25 UTC
From: la8ak.xnd@online.no
Message-ID: <3e2dee52.310299@news.online.no>
Source record: 38410

Hi

What I need is a local oscillator for a VLF receiver. The LO must cover 220-300kHz, so I suppose to use a 2.4576MHz xtal and 2MHz VFO and divide the output down to 220-300kHz.

The problem is that the boatanchor is xtal controlled telex receiver, but I would like it to have continous tuning. IF = 169kHz

Have a vague thought about using digital mixer, and it is an advantage to divide by two in the end. So if possible I would use a JK or D-type IC, preferably CD4013 since it is simpler to connect than CD4027.

Would like to hear opinions about a possible solution

Hi:

I would not recomend this but a crystals persent value is
measured in parts per million, if you get the largest value and
muliply by 10: the percent is now measured in parts per 10,000! I
order from supliers who advertise in popular electronics magazines,
are there any supliers who custom fit to the needs of the consumer?

PowerPoles are very good connectors. I did not have much luck crimping them with the inexpensive tools offered by West Mountain Radio because it slightly deforms the contact and makes it difficult to insert properly. I now solder the wire into the contact and that seems to work quite well. I expect the Anderson tool (around $100 as I recall) would make a proper crimp.

i believe squirrel cage motors rotate at a rate based on the 60Hz line freq as well as the number of poles in the motor rotor. if this is so, then you'd have to vary the freq of the 115V supply.

you can also mislead yourself into thinking that slower RPM means less vibration. the amplitude might be as great but the freq of vibration would be lower.

I am looking for ways to slow down the speed of a 115vac squirrel cage
motor.
It has a starting capacitor. I have put 100 ohm resistors on muffin fans
and that worked ok,
but with a squirrel cage motor, it tends to prevent it from starting up.
The reason I am
doing it is because I have plenty of air available, and I want to lessen the
amount of
vibration from the fan. The fan is mounted on the same aluminum box as a
Russian
GS-35B tube. I am a bit worried that there might be too much vibration for
the tube.
There is not a lot, but any is too much to me. I guess I could remove the
fan and hook a
short hose to it, but that is not as clean as the way I am trying.

Try something along the lines of a "dimmer" switch, obviously designed for the power load you are going to be using it for. When first starting it up, keep the dimmer switch in full-open/unrestricted setting and then "dial down" to the rpm's that you desire. I am sure that there is some type of product at the electrical stores that would serve this need.

Bob Lewis (AA4PB) wrote:
>PowerPoles are very good connectors.

Yes, they are very good, and the 35A size is good for almost all applications. This is the size West Mountain Radio uses, because ARRL recommends it as a standard.

Through my magazine column I have been recommending the same as a UK standard - it's on the 'In Practice' web site. Everybody, everywhere follows the standard polarity diagram from PowerWerx.

>I did not have much luck crimping
>them with the inexpensive tools offered by West Mountain Radio because
>it slightly deforms the contact and makes it difficult to insert
>properly.

Agreed - simply squashing the sleeve down flat will make it too wide to fit easily.

Another point when making connections to heavy twin wire: make sure that the two connector blades are *exactly* level and parallel - if not, it becomes very difficult to force both blades into the housing.

>I now solder the wire into the contact and that seems to
>work quite well. I expect the Anderson tool (around $100 as I recall)
>would make a proper crimp.

Probably any tool that makes a proper hexagonal crimp will be OK. Being an amateur, I use the heavy wire cutter to crimp the sleeve only just enough to hold it in place, and then solder.

Why don't you run the VFO directly at 220-300kHz, the required capacitance range is only 1.9:1, so this could be done without band switching. A 10 ppm frequency drift would alter the Rx frequency by less than 3 Hz.

The required inductances and capacitances would have to be quite large and hard to get, so indeed it would be nice to run the VFO at a higher frequency. Why not run the VFO at say, 16 times the desired LO frequency (3520 .. 4800kHz) and simply divide it by 16. The required capacitance range would be the same as in the previous case. A 10 ppm frequency drift would alter the VFO by less than 48 Hz, but the Rx frequency by less than 3 Hz.

The good thing with your original approach is that the required VFO capacitance range would be quite small, but the problem with your approach is that a 10 ppm drift at 2 MHz is 20 Hz and if you mix it directly down to 220 to 300 kHz, the Rx frequency drift would be 20 Hz and if a divide by two stage is used after the mixer, the Rx drift would be 10 Hz, still clearly much worse than running the VFO at the LO frequency or simply dividing it down to the LO frequency.

The down mixing approach is nice if you have to start the frequency range from (practically zero) as in audio generators with a linear frequency scale from below 20 Hz to 20 kHz in a single band (however with mediocre frequency stability).

The up mixing approach is nice for generating a narrow frequency band in the HF/VHF/UHF range with the good stability of a free running MF or low band HF oscillator.

However, neither of these cases match your requirement and in fact using it will just add to the drift without any benefits.

You can order them directly over the phone with International. Make
sure to have the Equipment model number and the channel frequencies
handy. I've used them for many years with great satisfaction!

Hi all,
I am looking for words of wisdom about the HP 5328B counter.
I have just bought one on ebay, with options 010 and 050.
It works, but the digits (and the other small leds) on the display
have a faint brightness, which changes with the number of them being on.
The more are on, the lesser is the brightness.
I suspect thet some driver chips must be replaced, but I don't have
a service manual.

Does anybody who has an intimate knowledge of this counter have
suggestions about this ? Which are the ICs to be replaced ?
Which is the procedure to mechanically disassemble the front panel,
behind which those driver ICs seem to be ?

Thanks a lot for any hints, suggestions, advices, etc.

I've seen Motorola radios do the same thing. The culprit has almost
always been the T/R relay at the antenna connector.

http://www.manualsplus.com

According to their search engine, the currently have a reprint
manual for the 5328B in stock at $55.00. A worthy investment, not just to
fix the existing problem but to keep the resale value of that counter up.

Good hunting.

The power is going into heating up components (sometimes
destructively). Don't try to transmit, except for brief testing, until
the problem is fixed.

Abrupt problems are generally easier to troubleshoot than gradual or
intermittent ones.

Quicky troubleshooting would involve:

Look for loose connections
Testing anything with moving parts (such as the relay above)
follow the circuit and look for toasted components or sections of the
board
testing or swapping out ICs
looking at caps and testing them

Usual precautions about working on live circuits
(i.e., don't get the nickname or the epitaph "Sparky")

Happy trails,

for those few of us still able to do home repairs...

A tip for parts, not for the vintage stuff but for the near vintage.

5/6 year old handie, ADI AT-600, blown vhf power slab. wanted a new one.

manufactuer has no spares, UK wanted £56, German radio shop.. £20 posted. 10 mins after arrival set back on the air.

Price was even better in Japan, only £15, with postage etc about the same as D

so, it used to be look west, now its look near east.

no wonder this country is what it is.

BN.

German firm:- Rainer Zimmer Communication
have no connection other than satisfied customer.

Go to westmountainradio.com, Look for the section regarding Powerpole crimping.
http://www.westmountainradio.com/supportrr.htm The proper crimp is NOT flat.
The crimper that they sell is Very good at making the proper crimps. It is a two step process that is recommended by Anderson.
I used to solder all my PP connections until I read this page. Now, if soldering is absolutely necessary, I'll use silver bearing solder instead of regular 60/40

OK es tnx for reply,
it seems to be a bad idea, will not use it as such, but it would have
been interesting to know what sort of products you get from the mixer,
and what sort of digital mixers is easy to hook up.
Will se what frequency range is most suitable for making a VFO

You can probably get away with it on some elements, but for some of the more elaborate elements (KXN1019B) it's best to let ICM rechannel the device. There are internal series inductors and misc. fixed value ceramic caps. that vary across the operating frequency range of the set.

Jan-Martin,
If you want to experiment anyway, an exclusive-or gate makes a very effective frequency mixer. It behaves similar to an analog double balanced mixer, but it requires (or I should say it 'works best with') with square wave inputs. For this reason, it can not handle input signals that have amplitude modulation.

I donno about a squirrel cage, but on some of the high RPM blowers found in older surplus equipment, I've used a series capacitor of about 1 uF to reduce the speed (and noise).

I have the Westmountain tool and I've read their instructions. No good for me. I had a number of bad results. I wind up making the first crimp and then loosening the connection by attempting to re-round the connector with the second crimp. Two options - loose connection or flat crimp that won't go easily into the holder. I gave up and went to soldering.

Did you get it? I'm a little confused by Motorola, as I had bought some assets from a radio/paging company that went out of business in Georgia that included programming software for about 60 Motorola Models (including the model you're looking for). I offered the CD I made of it all for $53.85 by Paypal, but Motorola made me take the offer down. Yet I see requests for this software all over the place, and if you do a hotbot search for "motorola programming software" you'll see at least a couple of overseas outfits openly distributing it over the internet! Anyway, I was just wondering if you got it, or got a threatening note from Motorola about it? I know I'm kinda peeved at sitting here with this stuff on this disk that's useless to me, that I paid money for, and I'm told I can't get my money back.

You could go to your local Home center or electrical storeand buy a fan
speed control like the type
used for ceiling fans.....except it may generate rf noise.
Good luck

As a mixer driven by digital logic, at the low frequencies around a couple of hundred KHz, I would use a CD4066 analog switching IC.

They have a nice dynamic range, cheap, and easy to drive.

That cap is probably a run cap, not start. I have a similar blower
that I slowed by reducing the voltage. I wound up at about 60 VAC -
runs nice and quiet now. I had a reducing transformer - try a cheap
variac if you can find one.

Jan-Martin,
Have you seen the digital VFO/MIXER in SPRAT No.101 ?

74HC04 as VFO running at 4-6.4Mhz into a 74HC4066 Mixer, mixed with a
DIL Xtal 24Mhz Osc and SUM divided down with 74HC4024
outputs are
28-30.4Mhz
14-15.2
7-7.6
3.5-3.8
1.75-1.9Mhz
875-950Khz

541. Need specs on Motorola 74N09 RF module?!? HELP

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-23 04:01:52 UTC
From: Tony <n5gpi@hotmail.com>
Message-ID: <QOJX9.63331$aG4.3821381@twister.austin.rr.com>
Source record: 38443

Anyone know where I can find the spec sheet for a Motorola Part
74N09 RF module. I believe it's something in the 800 or 900 Mhz band
but need good data on this module. Looked at Motorola sites and Internet
searches ... came up empty so far.

Thanks,

N5GPI

This sounds more like a power supply problem than a driver problem. I would normally suggest getting voltmeter readings first instead of changing chips. In this case, since you just bought it and probably had it shipped to you, I would suggest that you first pull the covers and check for loose chips, cards and cables. Then if the problem is still there, check voltages. BTW, do get the manual if you can.

544. Circuit help needed

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-23 04:53:18 UTC
From: Vic <nospam@bogusaddress.com>
Message-ID: <ojKX9.6835$t51.6662@news.bellsouth.net>
Source record: 38446

Read the posts re: Astron RS-12 amp PS (below). What a helpful group!

Well, the posts got me thinking; I'd like to install a cooling fan in the Astron 35M here, however I'd like the fan (3" 12v computer
fan) to come on only if the PS temp exceeds 110-120 deg F. Most of the time the PS has radios running in receive mode only and runs
cool so it seems needless to have a (noisy -- aarrrhhh!) fan running.

Does anybody have (or know of) a schematic of a circuit which would allow switching a 12v 1.6w fan on if temperature exceeds 110-120
deg F?

TIA
Vic

I'm with Paul in his suggestion of simpler alternatives; you could
feed that 2MHz oscillator into a decade counter. I once made a nice
PTO using the mechanism out of a car radio. I seem to recall rewiding
the coil to get the range I wanted. It was nice and simple, though
the tuning was by no way linear. Find an older car radio, and you could
probably just rewind the coil to run at 200KHz.

But I am intrigued by this thread. By digital mixer, I'm assuming
you are talking about a flip-flop that is in effect sampling the input
at the local oscillator frequency, rather than the mixers others have
suggested that are simply digital equivalents of analog mixers.

For some reason, the idea never got all that much coverage. I saw
it a few times about thirty years ago, and then people went on and
used things like XOR gates as mixers, which required a low-pass filter
on the output.

I don't recall seeing the scheme used to feed analog circuitry. The
times I saw it, it was inside a phase-locked loop, and once it was
used to move a VFO signal down to another frequency for feeding
a frequency counter.

The only ones I've seen used D-Type flip-flops. There is jitter
on the output.

Don Lancaster mentions it in his TTL Cookbook:

"Second, jitter in the output is inherent, for the Q output
can drop only immediately after clocking, thus quantitizing
the output square wave. The worst-case jitter is one-half the
clock frequency.

"For instance, if both clock and D signals are near 1KHz,
the worst-case jitter can be around a half-millisecond. If
the frequency difference is less than 50Hz or so, this jitter

is tolerable, but as the difference becomes larger, the jitter
becomes intolerable. Thus, the circuit works best when it is
taking a small difference between two nearly identical frequencies.

"Another limitation (sometimes a handy feature) is that the mixer
is harmonic sensitive. For instance, inputs of 10.000 and
10.030KHz will give you a 30Hz difference frequency. So will
10KHz and 20.030KHz or 30.030KHz, or any other harmonic difference.

"The circuit is very handy for signal generators that use frequency
synthesis, particularly where a counter goes on the output to
minimize the jitter."

He says basically the same thing in his CMOS Cookbook, but adds
"(Actually, the frequency jitter represents the sum of the
two frequencies. You normally can't separate sum from difference
frequencies in a single mixer; it takes sine and cosine channels,
singled sideband techniques, or something similar.)"

His seems to be both the most detailed explanation of the circuit,
and most pessimistic. The magazine articles I saw explained the
results but not why it worked. I suspect somewhere in old Motorala
databooks, especially the one about PLL's which I never saw, there
might be further information, because in their ECL PLL line, they
had a D-Type mixer specifically for this purpose.

That bit about phasing is intriguing, since when you are already
dealing with digital signals it's a lot easier to do the phase
shifting. Of course, when you get to that level of complication,
I'm not sure other schemes wouldn't be simpler.

The only ones I've seen of this type is nothing more than the
D-type flip-flop, with one of the input signals going to the
D input, and the other going to the clock input.

FWIW: You're probably safe enough using it for your own personal
radio(s), but trying to sell it or move it can get you into big trouble.

That's one of the reasons I started offering my services. There's a
LOT of Moto-boxes in the ham world, and the commercial shops are, in my
experience, often uneasy about programming such for the ham bands, or are
priced out of the realm that most hams are willing (and, in some cases,
able) to pay.

There's another factor. Setting up some radios, such as the early
Syntor X's, for ham service is more involved than simply reprogramming
the memory module. You may also need to do some retuning of the
receiver's front end, using a high-end sweep generator and spectrum
analyzer/tracking generator combo, because of the lower-end limit in
the radio's design of 150.8 in VHF, and 450.0 in UHF.

Since doing said retuning could very well affect the radio's type
acceptance for commercial service, and because there's no way to
guarantee performance of the modified radio to Motorola specs, most of
the commercial shops won't touch any such conversion jobs. Again, that's
why I started making it known that I would at least try.

My offer still stands. If the person that wanted the GM300
programmed still wants it done, and wants to get it done legitimately, I
am available.

> question my thought process. I do not have a amature radio licence, and
> very very little experiance with radio electronics, so if this will
> never work, you have an idea of how i could come up with such a think.

You really need to think about getting your license first. Many ham
clubs offer classes to help you do just that, and you can find a list of
clubs in your area through http://www.arrl.org
>
> so anyway, the CB transceiver i have is an Eversonic 23 channel. no idea
> what model it is as it does not say. i can provide a picture if needed.

<snip>

You would probably be better off hitting up a local ham swap meet
for a true 10-meter radio. CB rigs, although they can (in theory) be
converted, are far from optimal for such a purpose.

Again, though, you need to worry about your license first. Even if
you were to take on such a conversion project, the cost of the test
equipment required to make sure it works reliably (assuming the radio you
have is even worth the effort to convert) will far exceed the cost of a
used 10-meter transceiver.

> I do have some electronics experiance BTW.
>
> The reaon i ask this, is because if i am to go for my licence, i
> currently can't afford a transceiver.

Well, can you get a part-time job? Or are you already working? Most
folks I know in ham radio started out the same way (myself included), and
simply saved their pennies until they could afford to get at least some
of the gear they wanted.

> I know that i will most likely have to amplify the signal in order for
> it to be useful beyond my block (thats about how far it seems to
> receive, though the antenna is not correct, simply a wire streached
> across my room).

Worst possible antenna for anything but short-wave listening.

> Alternitivly, if anybody has a transceiver thay can sell for about $25
> (worth a shot).

Unlikely that you'll find a decent 10-meter rig, or even a 2-meter box, for less than about $100. Again, though, whatever ham club is local to you should be able to help, both in terms of getting your license and locating the nearest ham-dedicated swap meet.

Good luck.

I'm using this right now to detect phase alignment on two 1 MHz crystal
oscillators with a difference frequency of 1Hz.

The jitter on the oscillators is 34pS rms. This is sufficient to cause
the D flop to change state on one clock and reset on the next. It can put
out a burst of ones and zeros for up to 50 uS after the first one.

So if you use this mixer to detect phase alignment between two
closely-spaced frequencies, you might consider triggering a long one-shot
on the first output pulse. Then it works fine.

First of all, dimmers designed for resistive loads do not work well
with inductive loads, causing erratic triggering.

A squirrel gage motor usually operates 3-15 % below the synchronous
speed determined by the mains frequency, so reducing the effective
voltage does not give a large speed control range. Reducing the
voltage even further will deteriorate the motor characteristics
(torque etc.) very quickly.

The proper way to drive a squirrel gage motor at different speeds is
to use a variable frequency inverter. If it is a low power motor, you
could even use a sine wave oscillator, driving an audio amplifier
feeding a mains transformer connected backwards, but of course, the
losses are high, so this is only practical for low power.

You could use a thermistor in a bridge, followed by an amplifier and
relay to switch at a given temperature but a much simpler solution is to
fit an auto reset thermal switch.
I am looking at a catalogue showing one that operates at 50 degrees C
and resets when the temperature falls back to 35 degrees C. Cost is
under a dollar.

Be VERY CAREFUL with any ex-CB amplifiers with tubes. They may be
missing the most basic safety circuits.

I once worked on one for another local ham. He'd acquired it from an
estate; it had been sitting in his closet for a week, no AC mains
connected. (and had most likely not been operated for some time prior
to that.)

As a paranoid type anyway, when I lifted the cover I put a voltmeter to
the plates of the tubes. And was astonished to read 400 volts!

After discharging it (through a resistor!) I traced the circuit. No
bleeder resistor.

(my understanding is that didn't do much for the unit's linearity
either. Listening to 11 meters I can sure believe that!)

Derek & Vic,
Here are the URL's for my 2 favorite circuits for Fan control, the first
is a simple circuit, the second is more involved.
http://www.overclockers.com.au/techstuff/a_thermalfans/
http://www.e-insite.net/ednmag/index.asp?layout=article&articleid=CA200387

I know that there are a zillion other circuts out there to do the same
thing, I favor using a variable rate fan as this cuts down on noise, at
the expense of the KISS factor.
Bill Higdon

>
The value of the capacitor is the most important consideration, as
everyone has already noted. There is also another consideration,
namely the AC current-carrying capacity of the capacitor. Since the
capacitor is not perfect there will always be some dielectric heating
and a physically small capacitor may not be able to dissipate a lot
of heat. If your replacement capacitors smoke it will be for this reason.

Does anyone know a US source for low quantities (10 to 20 pieces) of 1 kV (or higher) NPO leaded disc ceramic caps? I'm looking for capacitors in the range of 15 to 220 pf. I've checked my usual sources (Digikey, Mouser, etc.) but no joy! The reference for the use here is Ed Wetherhold's (W3NQN) article, "Clean Up Your Signals with Band-Pass Filters". This was in May-June 1998 QST and also available from ARRL's web site. He references TUSONIX units but also thanks them in the footnotes for all the free samples. Good luck buying them in small quantities.

Thanks for any and all help
Glynn ..

If you're not already too far down the road with construction, try his
later designs in a 1999 QEX. They have a notch in each of the adjoining
bands *and* they use regular 500V silvered-mica caps. The filters have
the same 100-150W overall RF power rating.

This is in a UK catalogue for a company called CPC.
You can find it described on their website at
http://www.cpc.co.uk
Click on the link to Components, then Sensors and Transducers, then
Thermal Switches.
You'll see it is number two on that page.

I am sure that there will be component distributors on your side of the
pond with this item, or an equivalent.
Tandy also springs to mind.

Hope that helps

BTW, the crimping pliers are on sale at MCM Electronics for under
$10 right now. They also come on sale at HarborFreight several
times a year (I think the HF unit is this $6 crimping tool:
http://www.harborfreight.com/cpi/ctaf/Displayitem.taf?itemnumber=36411
but with no picture I am not certain).

> soldering.

Soldering can work, I've got a lot done that way. Only one
problem...

A fault or sustained high current loads can cause the joint to heat
enough to soften the solder. Then it all comes apart, or shifts
which results in a bad connection and more heat, etc. A secure
mechanical connection first is better.

It can be tricky. I noticed last time their instructions were now a
three-step process -- main crimp hard, side crimp less hard, and
then main crimp again to firm it up. A cheap hex crimp die would be
nice... But I need so many sizes!

New product idea:

Somebody should make a set of reasonably priced dies for crimping
everything, and then a line of tools that use those dies. Should
have "plier" size tools, long-handled tools, up to portable and
stationary hydraulic and pneumatic versions.

(OK, maybe "small dies" and "large dies" and the smaller tools can
only take "small dies" but the larger tools can take large dies or
small dies (w/adaptor?)).

Trouble with everything like that that I've seen, is the dies are as
expensive or more expensive than dedicated crimping tools, and the
tool holders for the dies are ridiculously priced. This isn't
rocket science, and it seems someone ought to be able to build these
for a reasonable price!

I would think that the plastic holders would also soften and deform. I use a fuse in the line that would blow long before the connector got hot enough to melt solder. I agree however that a mechanically secure joint is better - I just haven't found a reasonably priced tool to accomplish it reliably.

563. how to calculate and build a yagi???

Hello.

Ive looked around on some homepages but cant find the thing i need.

I need to find out how to build a yagi from the bottom.
There are allot of good final designs out there, but they are all for
amateur bands or WLAN,
what i need is some way to calculate the elements,driver,reflector, so i can
make the yagi
for what ever freq i want.

Can someone lead me to a homepage with such calculations?

Thank you.

It is even easier with a BF115 or BF173 - you may simply solder the
device to ground....
A friend (LA6AK) and I bought 125x MPS3394 back in 1970, and the
Motorola import agent had never sold so many devices to a private
person before..., but my friend wanted to do some experiments, so with
good cooling he could achieve 2W RF on 144MHz from a push-pull
amplifier using these two devices (believe the price was £0.06 each)

Went to Alexandra palace exhibitions in 76 and 79, but the folks seem
rather insulted when I tried to discuss such prces....

Later, mentioning that one worked for the Norwegian Telecomms helped
much in such direction, so it was usually easy to pay 100-off prices
even when the amount was just a few pieces, hi.

well, apart from sort of collector's value, those pocket books are not
much value, just gave the last to a friend, the tube info is extremely
scarce, and quite insufficient for any purpose.

It is a much better book, the German RTT from Franzis' Verlag, mine is
from 1982, but I've just seen a much better and later version
including pictures of all those old bottles, I bought mine in a German
bookshop, and the mate bought his in M�nchen recently

Doug:

Heed Paul's advice here, if what you have is in fact a squirrel-cage motor.

They are synchronous devices that run at (nearly) a multiple of the AC frequency that drives them. They are NOT voltage-controlled, and running one at reduced voltage will cause poor performance and overheating.

Perhaps you can live with that, but at least be aware of it. The proper way to change the speed of a synchronous motor is to change the frequency of the AC supplied to it. There are gadgets that will do this.

... Rich

Source record: 38324

The old 23 channel CB's are NOT good candidates for conversion to ham radio. Although some were converted as club projects. Mainly the GE board as I recall.

The major difficulty is they would be 'channalized' And ham ten meters is not channelized.

Also most of that type would be AM transmit/recieve. This means you would need to put it up around 29 mhz where most of the AM activity is. Again tho, not channalized.

Then the problem of the cost of crystals. If you happen to have a rig that required only 1 crystal change you would be in good shape. But being a older 23 channel you would need to change several of the mixer freqs. This could get expensive quick.

All in all I recommend you forget about it. Sorry.

You can scale a Yagi. For instance, if you want it for 188 MHz, find a design for 145 MHz, and multiply all dimensions, including (approximately) the element diameters by 145/188. This is actually how they do it, because it is difficult and inconvenient to build and test a large antenna.

574. FT707 intermittant TX / Distorted Audio

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-24 01:47:58 UTC
From: mike@corn2.freeserve.co.uk
Message-ID: <3e30922f.36537417@news.freeserve.net>
Source record: 38326

This may interest someone, its now repaired but it had me going ;-)
and I suspect that my other FT707 , of about the same age and usage,
has the same fault developing. This could be a 'stock' fault.

Rig = Yaesu FT707

Fault Symptom..
Reports of intermittant instability or distorted modulation on SSB TX
and intermittant wildly fluctuating output on CW TX.
Monitoring on a local RX confirmed this. Occasionally, only speech
Peaks were being radiated and on CW the 'drive' did'nt advance
smoothly until almost fully advanced and keying was found to be
effected. RX unaffected.

Fault Cure..
Traced the Fault to a Relay contact on the AF board, (RL3001 on
PB2095) which switches the Balanced modulator between TX and RX had
gone intermittant. This had a strange effect of being a non-linear
relay contact.. it would conduct normally when the signal was large
enough but at lower levels of drive it stayed completly open circuit.

575. Re: converting a CB transceiver for ham?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-24 02:21:32 UTC
From: Lou <tech@dp.net>
Message-ID: <b0qbm0$2u7$1@news.dp.net>
Source record: 38329

The Hy Gain boards were good for 10 meters. Also, I "think" if memory serves me correct, one or more of the "Sears Road talker" models converted reasonably well. Somewhere, I have a chart here, if I can find it of all the older CBs and/or PC Boards found in many models that would convert. I think too, it also listed the changes necessary for each at least as far as saying 2 crystals, retune or some sort of hint. It may have been more involved. I've not looked at it in a long time.

Thanks for the answer.
Ive try the program but it does not work for me, i keep getting very bad antennas.
could be nice if i just could type in 250mhz and then i makes a standard yagi and then
after that you could play with the design.

I wanted to build a beam for 250mhz, like 3-6elem, but the program keep giving me
extreem low gain.
I think i better look up a book.

Regards
Brian

when i calculate yagis, i take the following formula:

de=300/f/2
ref=de+5%
dir=de-5%

ref de dir
|
result in meters.

f=frequency in Mhz
de=driven element
dir=director
ref=reflector

this for three elements.

if i'm not wrong the spacing between the elements should be 0.2*l
((300/f)*0.2)

>running one at reduced voltage will cause poor performance and
>overheating.

that is true! but i have used my variac setup
on my homebrew for over 5 years
and 100ths of hours and never a had falure!
at 100 volts the speed just drops very little
and the noise level drops greatly
your only talking about 10% drop in the voltage rate which may be within
most moter(-+) specs

i may just be lucky
and ive heard some guys running a 240
fan motor at 120 with some luck
but a 50% drop in voltage would IMHO
cause a falure fast
>Perhaps you can live with that, but at least be aware of it. The proper
>way to change the speed of a synchronous motor is to change the
>frequency of the AC supplied to it. There are gadgets that will do
>this.

good luck

Usually the result of feed line mismatch or not building what the
model describes. Things like boom mounting and material can affect
gain as well.

>I wanted to build a beam for 250mhz, like 3-6elem, but the program keep
>giving me extreem low gain. I think i better look up a book.

How much gain do you expect? A 3 element antenna can be expected to
yeild around 7DB of gain, four may get you to 8 or slightly more and 6
will be in the 10-11db range. You can get much more out of say 6
elements but the reproduceability may be difficult.

There are no gimme a 250mhz yagi programs that will assure the
maximum gain without tweeking and even then you left to your designs
for feedline matching.

http://www.clarc.org/Articles/uhf.htm Check that site for simple
reproduceable designs that can be scaled to you desired frequency.
The 222mhz design is pretty close to to your 250mhz so scaling the
dimensions by .88 should work well. The 6 element design is around
11.2 DBi which is a very reasonable gain for that size. If that not
enough gain then scale one of the 435mhz 11 element amsat
designs to 250.

Something is wrong here. First, I think you mean (300/F)/2. But that won't
work either. More like 142.6/F meters.

==========
Not having the very latest ARRL Antenna Hanbook ,but the 18th edition , in
this edition you'll find section 18 describing a variety of VHF / UHF
antenna systems ,including a chapter on High Performance Yagis for 144 -222
and 440 MHz.
There is also a chapter on 50 MHz Yagi Designs.
The information includes installation advice.

Hi - I picked up a 13 pin DIN for my Kenwood. I'm just going to use pins 3 and 4 to get some line level audio from the rig. I could not believe my eyes when I got the 13 pin DIN - is there some trick to soldering to those pins? Or am I missing something here? Thanks - Scott.

A handy program is yagiu from http://www.nic.funet.fi/pub/ham/antenna/

It does OK at optimization. I have a version that corrects a few bugs
and has Linux executables. It even comes with source code.
Post here if you're interested in a copy.

Another approach is the quad antenna. They are easier to feed than a
yagi and have a little more gain.

73,
Jim

Scott,
It'll certainly make you 'bone up' on your soldering!
If you only intend to use certain pins, one option is to
cut off the pins you won't be using, near the pins you
will be using. Don't try to use 14ga. wire! (LOL)
Have fun...
'Doc

Scott,

I use a pair of Vise-Grips and gently hold the connector in them when
soldering. Grab the thickest pair of glasses you can find (2.50x) and go to
town. Take your time and it will be smooth sailing.

589. GAG CELLPHONE ANTENNA BOOSTER

I got the latest catalog for All Electronics in the snail mail (http://www.allelectronics.com) and on the second page they have an ad for a 'GAG CELLPHONE ANTENNA BOOSTER'. They're 2 for a buck or 10 for $4.00. The ad says, "The manufacturer claims that it improves the mobile phone reception but, in all likelihood, it doesn't do a damn thing. Advertised on TV and the internet for up to $19.99 each." It's only the size of a postage stamp, and is a stick-on sort of flexible printed circuit board with a bilaterally symmetrical pattern on it. I tried to find the ad on the All Electronics website but I couldn't find it (the ad is on page two), and it's not under cellphone accessories in their online catalog.

I googled for 'cellphone antenna booster' and checked some web sites, and they're selling for ten bucks or so, but I hope the FTC and/or FCC cracks down on them for false advertising. One site I visited had an actual graph of how much better the performance is supposed to be with this widget. I highly doubt the veracity of these claims. I'd like to hear some independent opinions of their effectiveness.

Well, when I wired up a RASCAL to my Kenwood, I just took a small pair
of diagonal cutters / wire nippers, and carefully trimmed back all of
the pins I didn't need until they were flush with the plastic
headshell. [Look twice or thrice, cut once!]

Aside from that, it helps to have a soldering pen with a small tip, a
steady hand, small-gauge solder, and one of those magnet-and-alligator-
clip-and-articulated-arms "third hand" holders to keep the plug in a
convenient, stable position during soldering.

Brian

Not sure what you mean by extremely low gain. A 3 element beam should give 5 to 5.5 db gain relative to a dipole AT THE SAME height, or something over 7 dbi in free space 6 elements could give you around 10 db relative to the dipole.

592. Re: Motorola Channel Elements Best place to buy??

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-24 20:06:59 UTC
From: Skipp can be found through sonic <notrealemail@yahoo.com>
Message-ID: <b0s6d3isj3@woodrow.ucdavis.edu>
Source record: 38345
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.swap

I too used International for many years, but they've become so expensive
that I sought out an alternative. I'm also a skeptic and had to verify
what I found would be a real fix.
A friend uses Bomar and gave me their number, I called and paid $10 per
crystal if I re-rocked the element myself. So I've done just that since
receiving my first order in.

I've now re-crystaled over 30 pairs of MSR channel elements on both UHF
and VHF using the Bomar units... very cost effective and so far, not one
bad rock. I use the recrystaled elements in my commercial (trunking and
conventional) dual mode and amateur repeaters.

I've had great service with International and only one receive element
(which they did) go just out of spec. But their prices have gotten way out
of line.

So consider Bomar as a real option, I've placed very large orders with
them in the last two years and everything received has been spec, on
time and cost effective.

I can also field MSR-2000 questions if you have any... I have over 50 in
service in many modes (including trunking) and have about worked out every
issue you could think up.

I have a conversion to an external controller (ham) work up on the
http://sonic.ucdavis.edu Amateur Radio page. You can Email me from any
of the web pages if you have questions. I've also done tone panel
connections and repairs of which I'll provide help as practical.

cheers
skipp

Strip the insulation of the wire to a length slightly longer than needed. Tin the wire. Cut the wire to the correct length. Go to the plug and put it in a holder of some kind (maybe a small vise) with the pins up. With some very fine solder try to just fill the little cup with solder. Let it cool. Then heat the pin back up. When the solder melts insert the wire in the connector, remove the iron and let cool. There will be enough wire in the cup and on the wire to make a good connection if done properly. That way you only have two things in the hands at one time, wire or solder while trying to deal with the plug.

596. 136kHz Field Strength Meter suggestions [PA0SE]

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-24 22:50:14 UTC
From: la8ak.xnd@online.no
Message-ID: <3e31bdc9.48964038@news.online.no>
Source record: 38348

Noted the construction on www.veron.nl/tech/lf/fsm/pa0se.htm
It is a DC-receiver using BF960 Dual gate mosfet, NE/SA612 product detector, it also have two OP-amps for meter and phone outputs. Isn't the uA747 the same noisy amplifies as 741? It seems not important here, but I always thought that uA741 needs at least 12V for proper operation(?), so a similar readily available noisy OP-amp is LM358.

The article mentions problem with DC-receivers and local osc.

Suppose the best ideas to avoid such are:
1) Use subharmonic anti-paralell mixer [RA3AAE type]
2) Use oscillator frequency on twice or higher than RF

It would be useful to have such a field strength meter, but when I am going to build something I wish to include some features based on what I find interesting to experiment with, and available components

Have lots of analogue audio level instruments with dB-scales, so it might also be useful to use such instead of a digital voltmeter.

Suppose I could go for the subharmonic mixer idea, is it possible to drive it from a CD4013 and use 'anti-paralell' CD4016 elements? But it seems that they may be constantly switched on.... hi

A Clapp osc(*) on 544kHz divided down to feed an NE612 is also a possibility, think magnetic stray is the problem on such low frequencies and operation on a higher frequency would solve stray problems, suppose the osc could use ceramic resonnator or 455kHz IF core.

NE614, MC3371 and other devices are also considered, but I haven't found the right idea to use such for this application, "sharp" selectivity is a must.

*) since everybody else seem to have discarded the Clapp-osc I love to use it, and find it very useful for my applications, it simplified the design when you take in account the problems it has and check that it is not really important for my construction.

Any other ideas to exploit?

Right on. Also the simple approach does not take into account element
diameter which at UHF is a significant factor. And the base design
does not explain how to feed it. Too many variables left out to
insure a good never minding a useable antenna.

We made active antennas, and LA7MI had problem with strong VHF FM broadcast station. He put a 10µH RFC in series with the input to the amplifier and the blocking was solved. The impedance on this point is very high. The active antenna now has a higher frequency limit around 40MHz now, but you could use a larger coil if you didn't need to listen on 10m and achieve higher attenuation for VHF signals

the circuit for my remote fed active antenna (aerial) is shown at
http://www.qsl.net/on7yd/la8ak.htm

The companion product (they were commonly offered together as a
" special offer") was the stupid little stick-on screen that goes over
the opening of the cellphone earpiece ... also a major fraud in my
humble professional opinion as an RF engineer of over 32 years.

(It's really scary that there are idiots out there that don't realize
that the RF comes out of the antenna and not the earpiece ...
and that claims that anything would "Protect you from 99% of
the radiation" just had to be bogus ...)

I love that they never want a cell tower within 20 miles of their
home or business, but complain of bad signal strength. The safest place
from RF is right under the tower. I was a broadcast engineer at a 5 MW
ERP TV station on Ch 55, (1749 foot tower) and we had trouble getting a
decent picture right under the tower, so we had to use a small antenna
to pick up a reflection from another tower a few miles away.

Philips pocketbooks are a problem, the sheets losen, while Telefunken
and other are better and sheets usually stays fixed, will still keep
it while the Philips pocketbooks has so short data that they are
really not much value.

Have a series of Philips handbooks from 1940's, 60's and 70's, 80's
showing tubes with a lot of data and curves, but they are difficult to
come by. Also see Frank Philipse' pages for good data, start with
http://frank.nostalgiaair.org/sheets4.html

Also have some even more rare books, the Piotr Mikolajczyk's Universal
Vade-Mecum (1960) Warzawa. It is rather heavy, suppose it is 2kg, and
R&#65533;hren Taschen Buch from 1954 in Leipzig DDR, also a very valuable old
pocketbook, and of course, they are not for sale.

A variation of the German phrase, "Hand book".
meaning not to fit IN your hand, but to be kept "at hand"

Anyone out there with the correct formula for the crystals on a Motorola
ht90 (ht440)?

I just picked one up and inside it has 4 crystals reading:
55387.50
55395.31
17206.01
17203.7

It transmists on 464.5000 ch 1 and 464.5625 on ch 2
Both simplex

Thanks for any help!

Chris

There is a nostalgic element for seeking these pocketbook, so in a sense what's in them is not so important. However, having said that I am looking for certain data and
I noticed the other day when I got hold of the Philips pocketbook for hams 1962 (very similar to the regular pocketbooks) that what I was looking for was missing. But, the information turns up in later editions. You are right about the pages coming out, the 1962 book has loose pages.

In fact, I might have been better off going for the Philips General catalogues. I think the pocketbooks are based on them.

Low side *8, IF = 21.4MHz actually.

609. Re: converting a CB transceiver for ham?

As the man previously pointed out, with your particular radio, it is going to be nearly if not impossible to achieve your goals. If you want on 10 meters, why don't you check around, some of the "older" 10 meter radios might be found for a reasonable price. Like the Uniden 2600 or some such rig.... I realize it may not be as much "fun" as creating but with crystals involved - you're talking quite a few bucks. By the time you get done screwing around with the crystals alone, you could have bought a 10 meter rig for a little more.

You do NOT need 1500 watts... To me, that shows the signs of a "power hungry" radio operator... I've worked the world on less than 100 - actually closer to 80... If your antenna system is decent, the radio working well, you will do well. You have to use the band, conditions and so on to your advantage. Save your electric and the money from buying an Amplifier. Ever hear of QRP? Many people find it a challenge to work the world on far less than even 5 watts. And they do it..... I've also used less than 80 watts. I've used as little as 10 watts and had decent contacts. I know people who've used 12 watts PEP SSB on 27 MHz (yes the CB band) who've talked to many nations. So - 1500 watts????? Believe me, you won't need it..... One other point, if you can afford to acquire a 1500 watt linear, then you obviously can afford a radio. Linears are not cheap. Not even a good used one. Just my 2 cents......

Best of both worlds: MSR2000 PA deck running on a Micor repeater
base.

I love the Micor RX and squelch system over the Mitrek. With a little
work the 110 watt PA and control system can be retrofitted to an
existing Micor base. Solves the obsolete PNP RF transistor replacement
problems as well.

Cheers

Pete

"Jean" wrote ...
> That is one heck of a pattern. How do you get it that sharp?

With 5MW ERP they must have an antenna with lots of gain.
Gain comes at the expense of pattern (coverage/dispersion).
The more gain, the narrower the pattern.
They are designed for (usually) omnidirectional horizontally,
and very narrow vertically to avoid wasting energy that won't
hit the viewers' antennas.

> Anyone out there with the correct formula for the crystals on a Motorola
> ht90 (ht440)?

Youbetcha.

TX = Crystal F times 27
RX = Crystal F times 8, plus the first IF (21.400MHz).

International Crystal can provide rocks for ham freqs if you want.
You should have the service manual and a service monitor handy to do the
alignment.

(SHAMELESS PLUG ALERT)

If you do not have access to either of the above, I have both, and
I can install the new rocks and tune the radio(s) up. See
http://www.bluefeathertech.com/rf.html

I need to get in touch with James Fenech or anyone who has built his "Wobbulator" as described at http://www.users.bigpond.com/James_Fenech/wobulator/wobbulat.htm. The problem I have is that I am unable to read or make out the resistor or capacitor values he has drawn around the 4046. Possibly if someone has a clearer jpg of the schematic or a parts list they could help me out.

Thanks in advance for all help,

Glynn also k4rki@arrl.net

618. FS: Old Radio Books - 1930's-40's

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-25 22:42:09 UTC
From: oldbooks78@aol.com
Message-ID: <20030125174209.18840.00000420@mb-fp.aol.com>
Source record: 38371

I currently have for sale the following old radio-related books. Postage is $2 for the first book, and $1 for each additional item (Media Mail within the US, at cost elsewhere). The books are:

Jordan, Edward C.; Paul H. Nelson; William Carl Osterbrook; Fred H. Pumphrey; Lynne C. Smeby; and W.L. Everitt (editor) "Fundamentals of Radio" Prentice-Hall, 1944. The 400 page hardbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. Gray cloth covers with some minor spotting on the front cover, otherwise nice. A nice early radio related text. Available for $10.

Institute of Radio Engineers "Proceedings of The Institute of Radio Engineers, October 1933" Institute of Radio Engineers, 1933. Volume 21, Issue Number 10. The approximately 200 page softbound book is in good+ condition, clean with no page tears or pen marks. Some moisture discoloration to the spine area paper, but not too bad, and not affecting the inside pages. Includes a foldout-out figure of oscillogram readings. Available for $10.

Institute of Radio Engineers "Proceedings of The Institute of Radio Engineers, December 1937" Institute of Radio Engineers, 1937. Volume 25, Issue Number 12. The approximately 200 page softbound book is in good+ condition, clean with no page tears or pen marks. Some minor wear to the spine paper, but not bad at all. Page tips in rear lower corner bent outwards somewhat. Available for $10.

Institute of Radio Engineers "1933 Report of the Standards Committee of The Institute of Radio Engineers" Institute of Radio Engineers, 1933. The 225 page softbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name on the front cover. Some wear to the spine paper, but not too bad. Page tips in rear lower corner bent outwards somewhat. A neat look at standards development for the radio in the early 1930's. Available for $10.

US War Department "Technical Manual - Radio Fundamentals, TM 11-455" U.S. GPO, 1941. The 140 page softbound book is in fine condition, fresh and clean inside and out except for a previous owners name on the front cover. A nice WWII vintage radio manual. Available for $10.

Everitt, William Littell "Communication Engineering" McGraw-Hill, 1937. The 727 page hardbound book is in about very good condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover, and a few passages underlined in pencil. A nice early text on the science of the radio. Available for $9.

Measurements Development Laboratory of the Sperry Gyroscope Company "Microwave Transmission Design Data" Sperry Gyroscope Company, 1944, Publication No. 23-80. The 215 page hardbound book is in very good condition, clean with no

page tears or pen marks, and a strong binding. Originally issued during WWII as a "confidential" document. Chapter topics include General formulae for concentric lines; Attenuation in concentric lines; Reflections and impedance matching; General formulae for wave guides; Attenuation in wave guides; Reflections and impedance matching in wave guides; Wave guide tees and bends; Wave guides filled with dielectric material; Dielectric material: Cavity resonators; and Measurement techniques. A neat early book on ultra-high frequency radio waves. Available for $9.

Beam, Robert (editor) "A Dictionary of Electronic Terms" Allied Radio, 1959. Soft Cover. The softbound 80 page book is in very good condition, clean except for a previous owners name marked out inside the front cover. Concise definitions of words used in radio, television and electronics. Available for $2.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks.

Dave

You can buy them on eBay by the gross for pocket change. (Take a look
at eBay's wholesale offerings.)

Of course they are an obvious scam, much as are many of the products
sold to the audiophile community. A few years ago they were being sold
on TV, but after an FTC crackdown, they're now usually seen as your
"free bonus" when you buy another product. Since in this case they're
being "given away", the FTC can't do much.

I'm now waiting to see the FTC crackdown on the claims of sellers of
"Ionized Bracelets" and "Magnetic Pillows."

The general public is too diverse to become technically educated on
the nature of these scams, but the government can go after the people
selling them nothing but hot air and ridiculous promises.

In the distant future, copper will be mined from veins of old automobiles. Theories will abound on what forces of nature concentrated the copper as purely as it will be found, and in such precise geometric patterns of fiber and twist.

Cheers!

Serge,

I haven't got through the whole list of links yet but I have found
many interesting sites.

...including lots of homebrew, a full wave EM simulator, a great RF
simulator 'RFSim99' and the CDG2000.

Merci beaucoup.

Mark.

Don't know where you're at, but I'm taking an electronics course at the
local community college (Solid State, but they offer DC and AC courses as
well).

The class is done really well, and community colleges are generally
pretty cheap. Worth looking into.

Just think, Monster Cable has made millions on the ignorance of the
average user paying ten times for patch cords and as much as 25 times
as mich a foot for speaker wire, all this when no lab to date has been
able to fine the least bit of improvement in all but the most extreme,
(read: unnoticeable to humans).

I saw a side by side test about 5 years ago with numerous "golden end"
Monster cables at 40 bucks for a left/right/video, and lamp cord or
the appropriate gauge provided equal performance to their best speaker
wire. This was for in home stuff, I can't imagine the car stuff is any
different.

"A fool and his money is soon parted...." Monster Cables and the
entire ilk of product are like skins for cell phones, they are more
for looks than anything practical.

My favorite is the Tektronix 465 (100 MHz dual channel with delayed
sweep) or the 464M (military version). It was once just about the
best analog design with the most intuitive controls. They now sell on
EBAY for about $100.

Any of the Heathkit O'scopes will do depending on the frequency you want to measure. See E-bay.

A surplus Tektronics or HP are industrial strength scopes but higher priced. These have calibrated vertical and horizontal settings where the general purpose scopes usually do not.

Some others are RCA, B&K, Sencor, others

I have to agree with your comments about the 465 but think a typo
slipped into the product number for the military version.
I suspect you meant to say 465M.
The 464 was a storage version.
If they are available the 475 (200MHz version) is another fine product.

For what it's worth, Win95 doesn't run DOS programs properly.
You probably want to locate a copy of MS-DOS 5.0
The most stable one in the bunch.

I will freely admit to being a Tektronix bigot. ;-)

Hunt around whatever ham swap meet is local to you, or on Ebay, for
a nice Tek 7603. This is a 100MHz mainframe which can take up to three
plug-ins. For general-purpose work, look for a 7B53 series timebase, and
a 7A26 series vertical plug-in.

For more sophisticated capabilities, and better bandwidth, check
out the 7704 or 7904 series. The 7904 mainframe has 500MHz bandwidth, and
I believe the 7704 is either 150 or 200MHz. For the 7904, you would want
7B92A and 7B85 time bases, and your choice on the vertical plug-ins.
FWIW, the 7A19 goes up to 500MHz.

If you want something you can use both bench and in the field,
check around for a Tek 465 or 475 series. The 475A is really nice,
especially if it has the DM44 multimeter option.

The only other thing I will add is this: Never sell yourself short
on any type of tool or test equipment. Buy the best you can possibly
afford, even if it means stretching a bit. It will be an investment that
will grow with you, and that you can resell later down the road.

Good hunting.

Almost forgot to mention some to avoid. Stay away from the
following:

Dumont
Most of HP's stuff (depends on the unit -- some of their scopes
were pretty good, though not the equal of a good Tektronix).
B&K
Sencore
Hitachi
Kikusui

Come to think of it, just stick with Tektronix (but avoid their
T922 model, and the 223x series). It makes things much simpler.

Ewwwww.....

PC's were never designed to be 'scopes. If the fellow wants a decent investment that can be handed down to another ham when he's done with it, avoiding PC-based "scopes" would be top priority.

How would you evaluate a used scope? For example, many of the inexpensive ones I've seen pictured on eBay seemed to have faded phosphors. How much does it cost to replace the CRT in a Tek? What else should a buyer watch for?

653. "Gain setting resistors"

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-27 07:56:38 UTC

Hi,

In the grid dip oscillator I'm currently building, the range of plug
in coils covers from 1Mhz to 280Mhz in 6 different bands with one plug
in coil for each band. Inside each coil housing, along with the coil,
is a resistor, the value of which differs for the different bands
covered. It doesn't appear to be in parallel or series with the coil
winding and is described in the notes as a "gain setting resistor."
Any ideas what the function of these resistors is? Is it in some way
intended to try to even out the response of the oscillator over the
entire frequency range?

Well, the FTC should be concerned if they're selling something that's
purported to do something, but doesn't. That's fraud.

I'm surprised that there was so little RF so close to the Tx. I would
expect that even at a neg 70 or 90 dB or more, at that high a power the
leakage would be strong enough to give some picture on a TV. Of course
you did say that it was not coax but waveguide up to the antenna..

At 720 or so MHz, all you have to do is squirt the RF out like a garden
hose, and it doesn't take a very large antenna to do that at that high a
freq. That's how they get such a high ERP.

Probably just as you say.
Up at the 280 meg end the GDO would be reluctant to oscillate. The resistors
will simply up the oscillator DC bias currents.
regards
john

I wouldn't be too sure of that. The FTC has cracked down on other scams
even tho they didn't actually sell something. If it's false
advertising, then they can do something about it (whether or not they
choose to do so is another question).

One of these comes to mind. The FTC came down on Philips last year for
taking too long on getting the rebates back to the consumers. And
another one is the apparent change in Plublisher's "Ed McMahon" Clearig
House ads which no longer claim that you've won a million dollars.

> I'm now waiting to see the FTC crackdown on the claims of sellers of
> "Ionized Bracelets" and "Magnetic Pillows."

I think they already have, or have warned them. If you go to Quackwatch
(.org?) and read the information about the Q-ray bracelet, you will see
that the Q-ray ads from a few years ago were making claims that they no
longer have in their current web pages (you have to go to their website
for those). They now say, "we believe.." as if it is not a claim, etc.
But they still have their infomercials on TV so they are apparently

still making big bucks off the devices even tho quackwatch tells you
they're a hoax.

> The general public is too diverse to become technically educated on
> the nature of these scams, but the government can go after the people
> selling them nothing but hot air and ridiculous promises.

Well, the public could just be buying something for the trendiness of
it, knowing full well that it's ineffective. Remember the Pet Rock?
Like, who woulda thunk that the consumers would fall for such a thang?

Another one that is no longer seen in the magazines (come to think of
it, we no longer see the magazines either), is the "Turns your whole
house into a TV antenna!", which is just a pair of 470 pF capacitors
inside a plastic box, with one lead of the caps connected to the 120V
plug pins and the other leads connected to the TV antenna twinlead
screws. Such a deal, at only $19.95!

I had a friend who fell for such things. He once asked me to
participate in the pyramid scheme that some co-worker suckered him into,
for $200.00! I told him that it was an illegal scam, and he went back
and got his money back from the scammer. That was back in the '70s,
when $200 was more like a thousand today.

I was walking by the local sound shop and the salesman and yuppie
customer were standing next to the customer's shiny new Porsche and he
was telling him that he would have to cut a hole into the door for the
speakers, and the customer got rather agititated and started to turn
pale when he heard the word CUT...

Aw, c'mon, Chip. You know that they scrap all that stuff out before
they crush them cars, and besides, the crushed car is in the shape of a
cube, not a vein. And another most important fact is that all those
'60s gas guzzlers were loaded onto ships and taken to Japan, where they
have no natural iron resources, and then were turned back into Toyota
Corollas and Datsuns, and shipped back to the U.S. Like, why waste
something that's already dug out of the ground? :-P

I love my Tek 465B, but I also like my Philips PM3055.

Both of them Just Plain Work. I think I paid $100 for the Philips
scope. I paid more than $100 for the Tek about 5 years back, but
it was till in-cal at the time, and so worth a bit more than
saverage.

I have to admit, I packed a Tek 465 for many years in the field. It
always worked except for the time a Airline tug ran over it. I had put
it in it's transit case and checked it rather than carrying it on. The
Airline bought a new scope for that one.

Hi Glynn,

You can email me directly at:

James_Fenech @ telstra.com.au.

Sorry the shematic isn't too readable, it was only put on the net on request of someone on the newsgroup. Someone in the UK was intouch with me a while ago and was trying to clean up the circuit, but I haven't heard from them for a while.

Basically, the timing components aren't critical. Using the smallest resistor allowed by your flavour 4046 (I used the 74HC4046), and a large pot will allow for the greatest range available.

I'll try to dig up some component values.

James.

You're going to load 98 or ME on a P60 with 8MB of RAM and a
420MB hard drive?

I'm going to load up just such a machine with MY CD copy of
WIN 95 B. I have a buttload of 8MB DIMMS for it.

The 'puter was free. I can always find a home for it.
I just might hook it up to my network and hook a printer
to it in another room...

Anybody want a 486DX/2-66? VLB video and I/O. 20MB of 30
pin SIMM. Must be 4-4MB strips and 4-1MB strips in there.
Soundblaster with MKE CD ROM is extra. ;->

Its a joke on the first book many of us older people learned to read from.

Dick and Jane were a boy and girl in the reading book. It starts off
something like:
See Dick, See Dick run.

I've 'inherited' a Motorola VHF Mitrek to repair. Am finding a number of small signal Motorola part numbered devices that are fried. Such as M9652, M9642, M9643. I've looked through some old ECG, NTE, etc. cross references but no joy. Does anyone know of a substitution listing for these devices?

73 de Jack

682. Wanted: NCX-5 Transceiver Service Assistance

I have a National NCX-5 MK II XCVR c/w AC Power Supply & Crystal Calibrator c/w Manuals that I would like to sell...BUT have a nagging problem, I hope someone has had and/or solved in the past.
Would like to sell it in working condx...as that would be the right thing to do!

The Radio works A-OK generally, but when you tune in a station calling CQ etc, and you key the rig to talk to him/her, on SSB or CW, I find that the Transceiver transmits 0.5 Khz OFF Freq from the Received signal.
Of course the other station tunes off his freq onto yours...you tune to hear him better..and "ring around the rosy" we go.
I've retuned the radio a couple of times, and am now seriously looking at components in the VFO or the Receive RIT Circuit.

If you have any this situation, any comments to either confirm my thoughts or point me in a better direction would be welcomed.
Thank You for your time
Norm VE3CZI

1/2" thick brass with lots of stainless steel bolts in every flange.
There was some RF under the tower, but there were so many reflections
you couldn't get a clear picture, just a very snowy picture with dozens
of ghosts. The tower was right next to the transmitter building, and
did a fair job of shielding the control room. We had five FM stations
on the tower at 1000 feet, and you couldn't pick them up clearly till
you were a couple hundred feet from the base of the tower. My first
night working at the transmitter site I drove up the long private road,
and my radio started playing. It had an open output transistor, but
the B-C junction was rectifying the RF, and it was quite loud, and
distorted.

In article <b14r49$6qi$0@216.39.177.51>, n7oo@theriver.com says...

> I've 'inherited' a Motorola VHF Mitrek to repair. Am finding a number of
> small signal Motorola part numbered devices that are fried. Such as M9652,
> M9642, M9643. I've looked through some old ECG, NTE, etc. cross references
> but no joy. Does anyone know of a substitution listing for these devices?

Don't know about a sub list, but I can tell you that the full
number for that class of devices (with a '9' right after the 'M') would
break out as 48-86xxxx, where xxxx is the four digits from your notes
above.

Example: M9642 is actually a 48-869642, M9643 is 48-869643, etc.

FWIW: I happen to know at least two of those devices very well. The
9642 and 9643 are general-purpose NPN and PNP devices, respectively. You
could probably substitute 2N2222 and 2N2907, respectively, and get away
with it.

Hope that helps.

I like to ask the "Computer experts", What was the code for setting
up a hard drive with debug, and seeing the blank stares. So much for an
IT department. :) I rebuild and sold a lot of XT and PCs, and went
through hundreds of used hard drives to test them using Debug. It was a
good idea to do a half dozen or more machines at once, because it took
so long to do a machine, and if one failed you stuck in another drive,
and started over. BTW, I still have a few 10 Meg Seagate SA-1004 8"
hard drives that predate the ST-506 interface. Geeky enough?

Hi out there. Anybody got pin data and frq/truth table for this chip used in an older VHF that onlt has US VHF frequencies. I want to add a switch so it can receive the International frequencies 63 and 64. Any ideas? Cheers, Renfred.
Remove (X) from xrenfred for correct email address...thanks.

693. Tank circuit question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-28 11:02:00 UTC
From: Wouter Visser <wfvisser@dds.nl>
Message-ID: <3E366329.9DFC7B9D@dds.nl>
Source record: 38296

Hi,

I was hoping someone could help me understand the following.
In a colpits oscillator, where the LC tank circuit is composed of an inductor (L1) and a split parallel capacitance (C1 and C2), what determines the optimal ratio between C1 and C2? I see how to calculate combined series capacitance of C1 and C2, given a desired frequency and inductor value. However, this still allows many combinations of C1 and C2 to obtain the required capacitance and I fail to understand why very often unequal capacitor values are chosen. In many circuits I examined, one capacitor would be many times greater than the other. Why?

Any help is appreciated,

Wouter.

694. Re: Tank circuit question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-28 11:28:25 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <v3cqbb95dr8t1b@corp.supernews.com>
Source record: 38197

The capacitors form a voltage divider which determines how much of the tank circuit voltage is fed back into the active device, and the amount fed back depends on the capacitance ratio. (The Hartley oscillator works exactly the same way, except that the voltage is stepped down by a tap on the tank inductor.) There are tradeoffs involved in how much is fed back. A certain minimum is required in order for the oscillator to oscillate at all. Once that amount is determined, increasing the amount of feedback will make the oscillator start faster, but will degrade the output signal purity and the oscillator stability. But enough feedback has to be used to insure that the oscillator will start under all conditions of temperature, voltage, etc. The actual amount required depends on the design of the rest of the circuit.

Dumont has made scopes recently? The newest Dumont scope I remember being
advertised must be 30 years old... and nobody was buying them then.
The company had really been out of gas and chugging along on fumes since
at least the 60's, and even before that they were very much the "budget"
scope.

I still have a DuMont 208, which was a pretty affordable scope for 1955 :-)
It probably cost less new than it cost just to ship a Tektronix from the
factory back then :-)

Tim.

Yes you are!!! I like to ask the "Computer experts" how many 16 bit
slots are in an XT. Actually, debug ran a routine in ROM that did
the low-level format. Fdisk and Format are the only two steps most
ever see these days.

I think DuMont's last gasp was part of a 3way government contract for
Miliatry portable scopes, HP's was a 180, TEK & Dumont I'm not sure of
the model numbers. I know a couple of shops that got stuck with the
DuMonts had accidents happen to the scopes to send them back and get a
TEK or HP scope.

The best advice I got (after the fact, unfortunately) was to get a
9-pin subminiature-D female connector kit from RadioShack. You want
the ones with loose pins. Make your solder connection to the solder
cups on the female contacts and then slip them oveer the pins on the
back of the DIN connector. You could also slip a piece of heat shrink
over the contact before pushing on to the DIN pins.

Regards,
Ed - N5KZW

Hi Bruce,

Looks like great information... I have some other things to add... You can actually call Motorola Parts and order them... using your credit card. Sometimes its cheaper and more practical, most of the time it is not.

You can order generic audio transistors from www.jameco.com simple enough, but people should stay away from ordering the basic transistors which act as saturated switches and often swapped in and out of the same circuits. You just limit your circuit when using SSw devices... their basic specs and labels are indicated on the Jameco Catalog pages.

So people, make sure to order audio transistors and not small logic type transistors so you wont beat yourself in the head when a circuit doest play as expected.

cheers

: <radioconnectionNO@cox.netspam> wrote:
: Best of both worlds: MSR2000 PA deck running on a Micor repeater
: base.

There are at least 3 or 4 different MSR PA decks... the highest power continous duty units are pretty much the same as the Micor PA units. The high power (non continous duty) 110 watt units need to be run light duty cycle or turned down to about 60 watts to keep from burning them up in busy applications. Many people use fans on them... not a good idea to trust them at full tilt using a fan... but turning them down to 60 watts and a fan is a great idea.

There are some 30 watt Canadian PA units which can output about 50 watts when run full tilt. I run them about 35 watts with no problems.

A lot of people mistakenly compare the Micor fast/slow squelch system (AS Board) with the MSR squelch system. You can set the MSR squelch system up to work just as good, or the same as the micor response. The MSR squelch is always sharp and responds well into the noise floor, depending on how your set it up. In reality, the MSR Squelch is much more flexible. I detail the setup in my External Controller to MSR text found on the http://sonic.ucdavis.edu Amateur Radio pages. Most people prefer to believe what they first read and what is the most simple to set up right out of the box. In fact, the MSR Repeater Squelch Circuit is more flexible in adjustment than the Micor circuit.

Cheers
skipp
http://sonic.ucdavis.edu

I'm not. I'm currently using a 2225 which somebody gave me for nothing
(and still not worth it) until I can find something suitable to buy,
but it seems to lose the plot completely on the higher timebase
settings. It's also not very user-friendly.
Before that I used a Hameg (German made) 20Mhz scope, which was a
piece of cake to use and gave marvelously stable, low-noise waveforms.
Both the scopes were made in the late 80s and no doubt the Tek cost
more, but I still got on much better with the old Hameg.

It turns out that for almost all circuits the "correct" gain is about
3. This is the loop gain including loading due to Q, strays, etc. This
can be derived from "large signal transconductance" curves of devices
operating in Class C (almost all oscillators). An old, but solid reference
for this kind of design is "Communications Systems" by Clarke and Hess.

The fat speaker cable supposedly affords better speaker damping factor
with solid state amps -- wonder what the damping factor was when we were
using tube amplifiers and output transformers?

Think that's bad? Take a look at http://www.essentialsound.com/ for the
most expensive extension cords in history.

One dude I worked with said he could hear the difference between gold
plated and nickle plated RCA connectors.

If you can't dazzle them with brilliance, baffle them with bullshit.

Older ICOM battery packs, e.g BP-3, BP-5 etc. These have indentations on the bottom that operate three micro switches in the BC-35 drop-in charger and tell the charger something about what kind of battery is put in.

Can anyone please tell me what the code is? What pattern of indentations corresponds to what info about the pack?

Sorry if this does not sound like homebrew, but I'm attempting to put together the best combination of bits that I have to make working packs, including combinations of cells that may not be what ICOM had envisioned.

I had one of these when they were brand new (just a few years ago :) I do seem to recall that there is a pot to bring the rec and transmit into alignment but I don't recall what it is. Perhaps some one else will know the specifics.

When I was working at a Army Depot in the radio shop I was told by a
Motorola rep that Motorola changed part numbers when they changed models.
Which basically means that a 2N2222 could have hundreds of different
Motorola part numbers.

FWIW department. I used to look up in the Sylvania ECG book in the
'reverse' fashion. Meaning Id look up common generic transistors and
compare them to the MPN.

It's amazing the BS that's outhere. If a different power cable makes a
difference, you've got a garbage power supply.

Anyone stupid enough to buy those, obviously doesn't know anything about
modern stereos, other than how to light their wallet.

There used to be an audio column in the old Radio Electronics magazine,
where the authour often pointed out the lunacy of those "golden ears" types
and the garbage they believed. One hallmark of them, is they don't accept
A-B tests as valid. But they maintain they can hear something in one
location and accurately compare it with another device in a different
location and time. Those guys are clueless!!!!

> I need a meter that will show FSD with a current of 200uA. I *have* a
> meter that shows FSD at a current of 0.56mA. Any suggestions, anyone?

1. Get a meter that's more sensitive. Or:
2. Build an amplifier. Or:
3. Hope that internally, for some bizarre reason, your meter is actually very sensitive but it contains an internal shunt resistor which you can remove.

#3 is unlikely, IMHO.

This is an instance of "can't get something for nothing." You can always bleed off power into a shunt to make something less sensitive, but the opposite doesn't work. Realistically #1 is your best option.

The 9642/9643 can be replaced by 2n3904/2n3906 They are the cheaper
versions of the 9570/9571's used in the HT220, etc. If you want smd go
mmbt3904/3906. I used all of these in the MT500, EXPO and other radios
including APCOR.

Thanks fellows for all of the useful information! Have substituted 2N2222
and 2N2907 for the NPN and PNP devices which have restored their operation.
Today in town picked up a 2N3819 N channel FET and we'll see if that makes
the ex-M9652 stage happy.

Hi,

Be a little careful about simply putting the 48-86 on the front end of an M number. It is a common thing to do and usually works. Unfortunately on the older gear (pre Micor) there are a couple of other prefixes. We found this out the hard way when we got in 5,000 RF power transistors at $37.90 each instead of a bunch of 5 cent small signal parts. I suspect they are still sitting in a Motorola warehouse somewhere .....

No, its not, but 95 only installs part of DOS. You have to do a
separate install of the rest of the files.

I remember one tube amp I owned that had a r/c network
connected between the output transformer secondary and the
drive stage just before the push-pull output stage. I guess
that took care of the damping.

Stop e-mailing me. I did not start this thread, and your sorry ass
is why I don't go to rec.radio.swap that group is nothing but a moron
pissing contest that I don't have the time to wade through. If you are
too stupid to ignore this, or any other thread that you dislike you can
just go back to sleep. People like you give hams a bad name.

Crosspost to enough groups?

Why not just use MS-DOS 6.22, FreeDOS or Linux with dosemu depending on
how demanding the exactness of DOSiness you need.

MS-DOS 6.22 should be $5 or less now days. Win95 is still about $25 on
eBay and the like. Linux and FreeDOS are free with no moral issues like
warez copies of Microsoft OSs.

727. Spider web wound coils??

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-29 03:54:49 UTC
From: j999w@aol.com
Message-ID: <20030128225449.22210.00000382@mb-ca.aol.com>
Source record: 38230

Anyone have any tips on making spider web wound coils for the AM BCB? (as used in xtal sets).

I need to build a very sharp bandpass filter to knock down local station overload on my MFJ1026 while I'm DXing the AM BCB. LC circuits built up from ferrite rods just aren't cutting it. I've got 5kw, 3 miles up the road on 1290khz that overloads the MFJ, and the best I can do is knock them down about 15db with a series LC circuit tuned at 760khz.That helps, but would like more. Stacking them two deep gives me around 20db, getting there, but I'm short on parts to do that. A band stop tuned at 1290khz will knock them down to a reasonable S9+20db (compared to a solid PEG!) , but the loss is way to great at 760khz to hear much of anything.

So, I'm thinking of using some spider web wound coils using Litz wire to improve the Q of my tuner. http://home.t-online.de/home/gollum/hcoils.htm

Ideas??

What kind of antenna are you using? If you've got a loop, how much does
putting the monster signal into a null give you? With the loop antenna
on my website I have little problem with local signals, even RFI.

Thanks for that. One question, though: does it have to be +5v supply
or can I get away with +9v? I've always avoided disdainfully any form
of IC, you see wherever possible and therefore wouldn't know.

I was most impressed too. How does one go about generating these
professional-looking ascii schematics? Is there a trick to it?

>Maybe I'd use a 200R pot for easier trimming
> of the 200uA shunt, +/-20% should be sufficient, right?

> very reliable number and a wide trim range is wise.

All I did was wind up a pot in series with a 9v battery, the meter and
a DVM until I got FSD. At that point, the DVM was reading 0.56mA. I
imagine the meter was designed to be 0,5mA, but... tolerance errors,
aging and all that. Still, having established the precise current
required for FSD, may as well use that to modify for 200uA.

The problem is that the _open_ loop voltage gain in the push-pull
stage is not very large, thus the closed loop output impedance is not
much less than the open loop output impedance. With a typical feedback
loop taken from the output transformer, the output impedance in many
tube amplifier could still be several ohms, so the damping factor
could be 1-5.

Hi,
I need to design a passive filter at 15MHz. The BW is 10MHz and I know that this is not a piece of cake. Normal single BPFs are not easy to be fabricated with available inductors.
I am trying a HPF + Buffer + LPF combination. The input/output impedance is 4K. I have chosen 100ohms a the output impedance of HPF and input of LPF to avoid large inductnce values. How should I use the buffer. Should it be hi impedance at input or matched to 100ohms and similarly at the output.

I used to have a magnetic pillow. But the darn thing kept sticking to the
plate in my head.

Spef, very nice indeed! I especially like the elegant round meter. Maybe I'd use a 200R pot for easier trimming of the 200uA shunt, +/-20% should be sufficient, right?

Hmm, a 0.56mA meter? Curious value. Maybe that's not a very reliable number and a wide trim range is wise.

Thanks,
- Win

With a filter that wide compared to it's center frequency, why use a filter at all? You're trying to pass from 10-20 MHz? What are you trying to do? Is this at a receiver input and you're trying to use it to receive 30, 20, and 15 Meters?

Indeed. As Walter has already suggested. It *is* a special meter made
by little-known company 'x' but badged by well-known company 'y'
specifically for their range of products. I took it apart to check,
but sadly no internal resistor. :-(
However, Spehro posted a useful little op-amp circuit that appears to
do the trick well enough. I've just simulated it with SPICE and get
-0.55u out for -200u in. I've no idea what the hell the units are
supposed to be in or what the signs mean, but it looks promising for
the breadboard. :-)

An LM7805 will turn 9V unregulated into 5V regulated. If you have
9V regulated, just change the 4K7 to 10K.

I don't have any problem with overload when using my loop, but I would rather use my EWE's and large verticals which have better gain and more sensitive for super low angle DX (South America and Europe).

A 'funny' number like 0.56mA might suggest that it is a 'special'
and maybe, only maybe, has an internal shunt already??

Cheers - Joe

Or a damaged, poorly made, or measured, 500uA movement. Around 1mA is
a good trade-off for ruggedness vs. sensitivity. It's possible the OP
forgot to take into account the drop across the internal resistance of
the movement, or the current shunt on this range of his meter has been
damaged.

Best regards,
Spehro Pefhany

Do you have it even when the antenna(s) is/are disconnected?
You'd better solve _that_ before you spend a lot of time
trying to notch it out on the incoming feedline(s).

Random thought: Can a person make a _suck-out_ trap
using crystals?

I couldnt find a connector for mine so I just pushed the wire into the socket. It has been one of those things I have been trying to get around to doing better but will probably will evolve into a permanent temporary fix.

Hmm. I sense a new market or three here. That cord doesn't do you any good without audiophile wiring going all the way back to the power plant. And it needs an audiophile-quality generator powered by an audiophile-quality dam or steam engine or nuclear reactor. Since it is unlikely that the power companies will install such equipment just to cater to the relatively small market of superior individuals who can understand the need for such things, then it becomes necessary to take the power issue directly in hand with an audiophile-quality diesel generator, which only meets spec if powered by audiophile-quality diesel fuel (can't use a natural-gas generator--can't trust the gas company to deliver audiophile-quality gas).

Then there is the audiophile-quality breaker panel that needs audiophile-quality breakers, and the audiophile-quality receptacle . . .

How much do you think one could get for wiring up a house with audiophile-quality power? $50K? 100? And how much should one charge for audiophile-quality diesel fuel, $50/gallon?

No, no, no! Nothing less than good, old-fashioned,
emotionally atisfying _coal-fired steam_ will do! Of course,
running homopolar generators for pure DC to feed the
toobs... oh, and they can argue the merits of distilled vs.
spring water.

> Then there is the audiophile-quality breaker panel that needs
> audiophile-quality breakers, and the audiophile-quality receptacle . . .

I see a stand-alone unit; no more "noisy" house wiring
issues, just feed the boiler and hear the music. Portability
is for plebes, after all.

One would have to frex ship in German coal for Bach,
naturally. Maybe they could be convinced to burn AOL CD's
when listening to Cage?

The 2200 series was designed to be made at low manufacturing cost, and in my opinion they cut too many corners on some of the models. I had a 2215 for a while, and got rid of it. It had things like overshoot that changed as the variable attenuator was adjusted. The specification was apparently carefully written so that these sorts of anomalies were still within the specs, but compared to the many other Tek scopes I've used, the overall performance was disappointing. I've had a 2246 for quite a few years now, and like it a lot. So some of the 2200 series scopes are definitely better than others.

If I were in the shoes of the original poster, I'd take the advice several people have given, and look for a 465. I believe it was the top selling Tek scope ever, and for good reason. The only weak point I'm aware of is that some of the switch contacts (for the lever switches) are heavily gold plated circuit board traces. When they wear out (which takes a *lot* of use), they can't be replaced, and if a worn one serves a vital function, the scope's a goner.

A whole new market indeed! I can just see the folks at the
refinery, paid minimum wage, of course, warping the little
benzene rings into chair or boat configurations, one at a time.
And making sure that the electron spins in all the C atoms have
matched spins, and so on.

"Audiophile-grade diesel fuel! Matched spins, all rings in 'boat'
configuration, *only* $5000/gallon. We're way ahead of second-
best!"

Somehow I don't think this fuel will be homebrewed.

Next we need to try to sell 'em low-noise batteries[1] for their
battery-driven all-DC glowbug audio gear.

[1] Honestly, I read a paper from NBS (now NIST) in the 1960s in
which the authors bemoaned the noise from their batteries,
and how it interfered with their very delicate measurements.

For a look at how far things have actually gone, look at:
http://english.aopen.com.tw/products/mb/Pax4b-533tube1.htm

It's not a joke picture. Here's the product description:
http://www.aopen.com/products/mb/ax4b-533tube.htm

756. Hughes germanium diode ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-29 21:40:35 UTC
From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <v3giimeu1is361@corp.supernews.com>
Source record: 38159

Going thru my junk box I found an small 2 1/2" by 3" envelope marked HUGHES DIODES Type MP 3016, Hughes Aircraft, Semiconductor Division, Culver City, CA. I think the MP means matched pair. Inside are two pretty standard looking glass diodes like the old 1N34, 1N60 but they are color coded brown, white, gray meaning ?1N198. My search for MP 3016 or 1N198 reveals nothing. I wonder if they're audio, video or lo microwave. Does anyone out there have any info?

Is that the onboard graphics processor?? Designed to give the PC an
authentic feel for when your running an ENIAC or EDSAC emulator?? ;-)

My 1981 D.A.T.A.Book says the 1N198 is germanium. PIV = 80V,
10uA@10V@25C Ir, 1pF cap, 80mW diss, point contact. Looks
like plain old generic part. Ten manufacturers. The databook
is silent on the MP 3016; knowing HAC Semi, it might be a
special marking house number for a customer.

I can definitely knock their sig down farther with a notch filter, but I also knock down the rest of the band by quite a bit. Hence the need for a narrower device.

No problem with 'no' antenna, but with wires, that MFJ1026 gets clobbered.

That's like when I went to high school, there was a 5kW AM transmitter
in a plant nursery next to the high school. Some people said that you
could hear the voice of the radio station if you put your ear up to the
door, which was wood coated with a sheet of steel. I never could
confirm that, tho. The guys and I went over to the radio station, but
there was a whole big bunch of bees swarming so we got the hell outta there.

I first saw this in ... September, 2002, IIRC. I boggled then,
and I'm still boggling.

4k is a fairly high impedance for 10-20MHz. 2pF is about -j4000 at
20MHz, so if you aren't careful, stray capacitance will mess you up.
If you have a choice, I'd say to work at lower impedance: 100 ohms
should be OK.

What sort of attenuation do you need beyond the passband? What sort
of passband ripple can you accept? What sort of phase linearity do
you need? Those things will determine what types of filter and what
filter orders will work for you. I recently did an 11th order
elliptical lowpass filter at roughly those frequencies, at 50 ohms,
and all the component values were reasonable: ~3/4" diameter coils
with between 4 and 7 turns, and little C0G ceramic caps. It's really
helpful if you have a network analyzer to aid in tuning the filters
up. There's not necessarily a need for a buffer between the HPF and
the LPF.

Cheers,
Tom

Hi Group,

Anyone doing anything with converting old micro-wave ovens to 2.4GHz amplifiers for AO-40 Satellite work?

Also, is the power supply components any good for making a HF linear? I see alot of old units at the flea markets.

KJ4UO

You may think you're kidding, but on one of the golden-ears wacko audio
newsgroups someone cited a magazine review where the guy actually had
all his home AC wiring replaced (all the way out to the pole). Of course, at
that point you are transformer-isolated from the rest of the grid(!)

"Run" as in "execute", silly.

Back in those days, there were several programming 'languages' that
"compiled" the source code in to a compact representation, and which
required a "run-time interpreter" to actually execute it. This provided
for 'hardware independance, because you could move the "compiled" programs
to any system where the 'run-time interpreter' had been implemented.

A couple of the better-known examples of this approach were "Business Basic",
and "dBase".

Both of those languages provided a MS-DOS program called "RUN.EXE" which _was_
the "run-time interpreter". You really _did_ do things like "run invoice.prg".

>Remember the big upgrade with WIN95? Being able to
>download a file and send it straight to the floppy drive!

I could do that under DOS 1.1, using the KERMIT comm. program.

I even did it on machines that _did_not_have_ a hard-drive. Sometimes I was
writing to the 'current' floppy, sometimes to the 'other' one (when the
machine was "loaded" enough to have *TWO* floppies, that is. yeah, once
upon a time, that _was_ a "high end" machine :)

I had to write a special program to do it on a "PC jr", because _that_
box was deliberately crippled and couldn't service the serial-port
interrupe _while_ writing a sector to disk. Thus, had to do an [XOFF]
before issuing the disk write, and an [XON] after it finished.

The _really_ funny one was to, in a computer *store* -- praticularly one
like the computer department of a Sears (where the help usually was *not*
terribly computer-literate -- set the prompt to the 'screen erase' sequence,
after making sure that 'ansi.sys' was loaded.

It was simply _amazing_ how many supposedly "knowledgable" salespersons were
utterly unable to cope with, and/or "fix" that particular "gotcha".

I never used a DTC drive. I looked through an old reference just now though, and it looks as though DTC used the same command as Western Digital.

IIRC, the original 10meg drive that came with my XT used the command g=c800:1

It's been too long that I don't recall the difference between the :1 or :5 part of the command, and can now find no reference to the :1.

I still remember "upgrading" to a 30meg drive that cost me a fortune (for me) of $300 at the time, and hearing the steady click, click... as the stepper motor slowly rotated during the low-level format process.

I have a better idea. in three parts:
1) why don't you *stop* posting in HTML, since it just makes your posts
an average of *FOUR*TIMES* larger than they need to be?
2) recommend you learn to use the 'killfile' capability of your newsreader,
so you can pre-emptively 'ignore' threads and authors that bore you.
3) recommend that the rest of the world consider using _their_ killfile
capabilities to 'ignore' those with their nose so bent out of shape
about a little humor.

I'll start.

plonk

Neither is MS-DOS (it's merely a 'glorified progam loader').

It is said:

"Windows is a 32-bit graphical interface,
for a 16-bit extension,
to an 8-bit operating system,
written for a 4-bit processor,
by a 2-bit company,
without 1 bit of skill in what they were doing."

Methinks the description is somewhat _generous_.

I had the loaded XT with 2 360K floppies, 20MB ST225, multi I/O card,
CGA adapter and CGA monitor. I had a 286-12 with EGA and a 40MB ST4051.
I had a 386DX/40 with 2 Maxtor full height 140MB XT1140 drives. The
damn MFM cables would get flaky over time. My first IDE drive bought
around that time was a 1.2GB that cost $250. Being in the business,
I get good stuff at the right price. No Pavilions or emachines or
Dells or Gateways or Aptivas for me. You can buy that sh!t. I won't.

I'm ending this crossposted thread here. Have a gooder.

Some controllers had "advanced" utilities accessible via

-g=c800:8

and the "c800' wasn't necessarily reliable. it could be "whatever"
the base address for the on-board ROM was set as. usually via
jumpers, so you could have more than one controller in the system.

>Digital.
>
>IIRC, the original 10meg drive that came with my XT used the command
>g=c800:1

impossible. the first 5 bytes of the ROM were 'reserved'.

the first 2 are an "identifying signature" for the 'start of ROM'
hex "55 AA"
the 3rd byte is the size of the ROM in 'paragraphs'
the 4th and 5th are a 'short jump' instruction to the start of the
ROM 'power-up initialization' code.

The "POST" bios code scans all 'high' memory, looking for the 'signature'
on paragraph boundaries. when it finds one, it a) does a 'far call' to
{base_address}:3, and b) when that returns, skips over the declared size
of the ROM, before continuing the search for more 'signatures'.

Sometimes there were 'multiple' entry points in the ROM, usually at
3-byte intervals up from xxxx:5. I know I used some that had "advanced"
configuration stuff at xxxx:8.

These days, "I dunno" applies. I don't keep that stuff memorized.

However, consulting my Unix 'termcap' file, it looks like the
requisite magic is:

prompt=$E[;H$E[2J

the first escape sequence 'homes' the cursor (top-left corner),
then the second one does an 'erase from cursor position to end of screen'

I don't see why you should have to use a regulated supply at all. The
PSRR for a LM324 at this gain is good enough that a simple bypass cap
should be be sufficient. Am I missing something?

I've selected the resistor in series with the meter to allow only
moderate over-current. If the power supply voltage is varying all over
the place, it might saturate and give incorrect readings or give it
enough current to bend the needle. A 25 cent 7805 is an effortless and
reliable prophylactic against such problems, without requiring any
more information from the OP.

Best regards,
Spehro Pefhany

Hello,
I need to mix down an incoming 900MHz signal. For downconverting I want to use the MAX2680. Does someone has experience with this component? Or does someone knows a better mixer than the MAX2680 for this frequency?

Thanks in advance

Steffen Brink

Not really possible, but I once saw a site where a HAM had locked a
microwave magnetron and did some experiments. I think the verdict was
'lots of power, but too bloody hard to use'.

> Also, is the power supply components any good for making a HF linear? I see
> alot of old units at the flea markets.

Yes, but they are also a great way to kill yourself, particuarly if you
take out the shunts, you can pull amps off the HT into a nice plasma flame.

Thanks guys,

So, predicting the actual total loop gain of a real world design is going to be difficult due to the many unkowns (stray capacitances, Q, transistor gain manufacturing spread etc), the best procedure would be to empirically find the smallest value of capacitor in the feedback path that will provide reliable operation?

Regards,
Wouter.

Good thinking. I usually use a 78L05 in such spots, a convenient
TO-92 just like another "transistor," etc (p/n = LM78L05Z). Also,
whereas the 7805 takes about 5mA quiescent current, the 78L05 only
takes 3mA. Hmm, the I wonder if the OP's 9V supply is a battery?
An even lower current might be appropriate, such as 0.2mA from an
LM2936Z-5.0, etc. Furthermore, a battery can sink to only 6V at
its end of life, but the 2936 is also a low-dropout regulator,
under 200mV. http://www.national.com/pf/LM/LM2936-5.0.html

Oops, oh-oh, I feel another one of those increasingly-frequent
depletion-mode MOSFET attacks coming on!

I edited Spef's drawing, replacing the 4k7 with a Supertex LND150.
http://www.supertex.com/pdf/datasheets/LND150.pdf Hmm, perhaps a
470R in the FET's source lead would be a good idea, to limit the
maximum current to about 0.8mA, instead of 1.5 to 3mA.

Thanks,
- Win

>reliable operation?

From what I recall, most definitely. Unless you're working to a proven
design, of course. Paracitics/strays lurk everywhere at RF; not just
on circuit boards and component leads but within components
themselves. Some proven oscillator designs use the internal
capacitance of the active device to provide all the feedback necessary
to function without recourse to external f/back circuitry and you'd
wonder how the hell they work if you weren't aware of that. It depends
to a great extent on the characteristics of the active device used.

Some chap also stated a while back on this group that those
nice-looking, beefy transformers are actually no good for use beyond
20 minutes at a time as the primary windings have too few turns. Seems
a shame. :-(

I did mine from memory. ESCAPE LEFT-BRACKET 2 J came to mind.

ESCAPE LEFT-BRACKET ; H. That's move the cursor home.

I wrote ansi.sys screens for people back then.

OK. Back to the 21st century. I'm done with this thread.

I have what's left of a crowbar that has a note on the pcb: "73 mag 8/79". There is an unidentified SCR on the board and a couple of components missing which must have been a pot and resistor in series used to adjust the firing voltage on the gate.

Would anyone have a copy of that issue? It probably has the circuit and component values in it.

I'd appreciate it if you could tell me what the values of those missing items might be.

Perhaps you should write to Digikey and ask them to carry the Supertex
line. I, also, have an issue with the MOQ for SMT parts, and an
application where they are close to the only game in town. I found
them receptive (though they've not yet done it) to taking on the
Lumileds line.

Best regards,
Spehro Pefhany

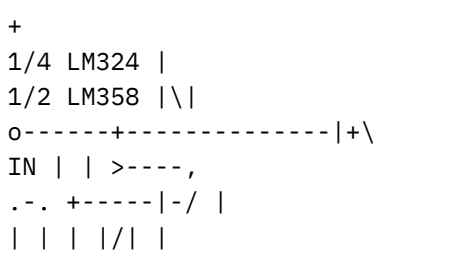
He he, I was just waiting the moment you couldn't refrain...
However a simple more common Jfet is enough in this low voltage app.
An even more common 5.6V zener and a resistor will do the trick with less
dispersion on the current limit.



```
390R| | | | |
'-' | === |
| | GND |
| | |
| +----->Z------+
| | 5.6V zen |
| | |
| | | |
| | | | select for 3V drop
| | | | (with the meter)at 0.5mA
.-. | .-. |
Span +-->| | +-----( )---'
Trim 500R| | | .-. - '-' +
| '-' | | Meter
| | 180R| |
+----+ '+'
| |
=== ===
GND GND
```

Fred.

Well, in a true story:

Some years ago, a world famous university in Cambridge Mass, founded
in 1630, was building a new Earth Sciences Building.

Because one of the labs planned for that building was going to do
extremely precise measurements of the Earth's magnetic field, they
very carefully made sure all of the building fixtures, plumbing,
electrical, hardware and so on, were made of non-ferrous metals,
avoiding steel and iron which would interfere with their measurements.

Then the exterior of the building was done with red bricks.

(The red color in bricks is from iron oxide.)

This minor goof of overlooking one mundane material made all of the
other careful precautions meaningless.

In a personal true story:

I worked in a semiconductor processing lab, and one of our measuring
devices had a terrible problem with inconsistent measurements. It
measured device profiles in hundreds or dozens of &#65533;ngstroms, with a 5
&#65533; resolution. There was too much vibration, not only in the building,
but from the highway outside. The higher frequency vibrations from the
building were dealt with by putting the profilometer on a heavy marble
table, but we were still getting problems with low frequency
vibrations from trucks hitting potholes in the highway (we could hear
this as well, from 300 yards and through two glass walls). I ended up
adding a secondary platform suspended on a rubber which absorbed the
low frequency vibrations. This combination finally solved the problem,
and the device was able to produce measurements within its specs.

Sometimes you have to be that picky.

Happy trails,
Gary (net.yogi.bear)

Because that way I can't make $498 a gallon selling it to audiophiles,
silly.

I'd prefer something that didn't depend on wiper resistance. Perhaps flip
the positions of the 500R and the 390R (and tweak the values as required)
and have the wiper going to the + input of the op-amp.

Charles

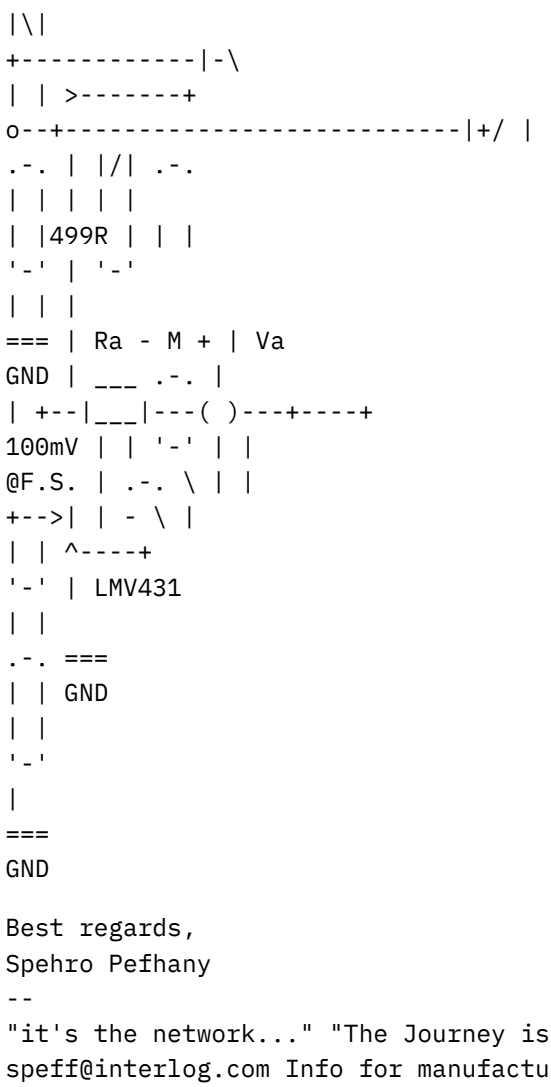
Sure. It's ok as-is for the purpose, but that's an improvement.

This clamp circuit might be a bit (again unnecessarily) better, and
will work to a low voltage if it was desired to make it run from a
couple of AA cells (with a suitable op-amp, of course).



Best regards,

Hi Francois,

If you are careful, you can measure frequency with a CRO
to maybe 2% best accuracy, but it's like using a srewdriver
to drive a nail.

Always try to use the right tool for right job.

Chuck

Hi

I'm wondering if I can use an oscilloscope as a frequency counter. If I can, how does it compare, when it come to precision, to a freuency counter?

Since I never used neither of these instruments, maybe my question dosen't make sense to the more experimented.

Thanks for any input

Francois

That's one of the basic uses of an oscilloscope, determining the frequency of a periodic waveform. Use the scope to determine the time for one period of the waveform, take the reciprocal and you have its frequency. As for precision, a scope can't compare to a crystal timebase frequency counter with a digital readout. Most of the time a scope determined frequency is close enough for me, just depends on your accuracy requirements.

Oh, come on now. You really think that audiophiles growing their own plants
for fuel oil wouldn't jump all over specialty plant food and fertilizer?
Much easier to store, sell, and ship than fuel oil.

An oscilloscope makes a fine frequency counter, as long as you don't require a great deal of precision.

It's not unreasonable to measure frequency in an amateur shop to within a few Hz at HF using a frequency counter. So, 10 Hz at 10 MHz is around 1 part per million. Getting within one part per 10 with a scope takes a little care.

On the other hand, if the waveform is ugly, as it often is when you are in the midst of homebrewing equipment, you can often get very misleading results with a frequency counter. If the waveform is unexpectedly weird, the frequency counter can easily be off by a factor of 3 or 4. Since you can see this weirdness on the scope, you can't be mislead as easily.

With f = 1/t? Yes, it can be done. Won't be anywhere near as
precise as a counter, though, unless you've got one of the digitizing or
digital storage 'scopes that lets you put cursors on the wave to measure
the time between peaks.

> Since I never used neither of these instruments, maybe my question dosen't
> make sense to the more experimented.

It makes me ask why anyone would want to use a 'scope for anything
but rough frequency measurement. If you need precision, use a counter or
service monitor.

Almost forgot to add; Many 'scopes, those from Tektronix included,
have an output jack for a (somewhat) cleaned-up version of the vertical
input signal. I've tapped off this for a frequency counter before with
great success.

Another option: The Tektronix 7000 series has a frequency counter
plug-in available (the 7D15) that can read the frequency straight off the
selected vertical input with no additional cables.

I have alot of trouble believing this story because Iron oxide is
basically non-magnetic. They might have had enormous trouble from
any electrical system because of the radiated fields. Or maybe
even the induced current as any longish conductor rotates with the
earth through it's magnetic field.

What do you think the first magnetic recording tapes used????? Iron oxide is magnetic. That's why it was the principal coating used in magnetic tapes, drums and disks for many years.

Power wiring is inherently balanced as current flowing out to the load on the black wire (blue in Europe) flows back to ground on the white wire (brown in Europe).

I hold a patent for a chip probe-card that allows one to measure femto-Amps. When we measure stuff that low, room light, or even someone walking by 5 ft away would completely swamp the measurement. Bigtime Farady and light shielding. But never any particular problem from power mains wiring.

Agreed. But there is 1-5mm separation between the conductors which
are almost always parallel and not even twisted. There will be
residual uncancelled fields except perpendicular. Perhaps only 0.33%
uncancelled at 10ft, but thats still alot from a wire carrying 5
Amps. Less in Europe because the Amps are lower for the same Watts.

You might have missed the mains if you were doing DC measurement!
You eqpt might have just averaged the 50 or 60 Hz, and most loads
draw equally + and - parts of the curve.

Why B&K? I used a 5 MHz job in a TV shop years back, and it was as good
as any other 5 MHz unit. I also borrowed a 100 MHz unit from a friend
and did NOT want to give it back, but he refused to sell it. That one
was a nice scope, with much nicer triggering than any Tek I've used.

Ewww. My bro-in-law asked me to try to fix his expensive Heath scope. It
drifted so badly you could not adjust the DC balance. Triggering was
bad enough that it might as well have been a recurrent-sweep unit.

840. crystal set speaker

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-01-31 04:33:21 UTC
From: Doug <dougmelissa@tm.net>
Message-ID: <l0n_9.49$Bd.77621@newshog.newsread.com>
Source record: 38143

A design for a crystal set calls for a 2000 ohm speaker
and says a smaller, 8 ohm type will not work.
The one for my walkman measures 26 ohms, the small
speaker from radio shack measures 8 ohm - measured
with ohmmeter (is that correct method?).

Can someone explain why a set would work with a
large but not small impedance speaker?

Finally, where can I obtain a 2000 ohm speaker?

Thanks,
Doug

841. Re: oscilloscope as a frequency counter?

It means that the audio energy source in the crystal set can put out only a half milliamp for every volt of output. (and it puts out only a tiny fraction of a volt) An 8 ohm speaker needs 125 milliamps per volt. You can put a 2000 to 8 ohm transformer upstream of your 8 ohm speaker and approximate the 2000 ohm speaker.

The characteristic of a xtal set is that it's output voltage is very
'fragile' (or high impedance as we say). Directly you hook up anything
low impedance such as a 8 ohm speaker to it, it will overload the
set's capacity to provide any useful output power and you'll end up
with zero output. OTOH, if you use a 2000 ohm speaker as a load, which
is much higher resistance, you preserve that delicate output voltage
from the set and you should be able to get some modest volume out of
it. Crystal styluses on old record turntables are the same. They
produce a very impressive 1v output - until you try to draw any power
out of it, that is.

Twisted power cable is not hard to come by and since this lab was for
measuring (IIRC) the earths magnetic field, it would be a simple matter to
filter out the alternating field from power wiring.

IA, a 741 or a 301, or even a TL071 or any 8pin single should work fine,
the meter movement it going to be the limiting factor of its accuracy if
you use a good quality trimmer and calibrate it properly. You could
even make the op-amp out of three discrete transistors if you wanted to.

The reason that you want to use a scope as a frequency counter can be quickly seen when you work with switching power supplies, opamps, regulators etc. -- often you are looking at millivolts of transients that you want to read just above the noise level. If you can identify the frequency (period) of the transient you are on your way to the filtering solution.

For looking at a nice clean sinewave the 7D15 for the Tek 7XXX is a nice device.

The input common mode voltage range of some older op-amps (designed
for bipolar power supply) did not include the supply voltages.

When running these op-amps with a unipolar supply, the input voltage
is _at_ the negative supply voltage when no current is flowing in the
shunt. If you connect the test current the wrong way, the op-amp
non-inverting input will be more negative than the negative supply,
which can cause some problems.

Op-amps such as the LM324 are designed for unipolar supply and the
input voltage range includes both the supply voltages, so it is safe
in this respect.

You can use half of an LM358 (a dual) but they are all about the
same price per chip. There is no *jellybean* (universally popular,
cheap and no-brainer first choice) single-supply op-amp
that I can think of- if you were using something special (for
example, so you could get more battery life with battery power),
you could look at CMOS amplifiers such as National's LMCxxx
series. I'm sure there's something nice in an SOT23-5. ;-)

Best regards,
Spehro Pefhany

It isn't the purist approach, but a FET stage would let you use commonly available walkman type 'phones. Unless you get lucky at a HamFest, the old high impedance phones are difficult to find.

Last time I checked, they used iron oxide for the magnetic coating on cassette tapes, VHS tapes, etc., etc., etc.

Also, if you fire the bricks to a temp above the curie point of the oxide, when it cools it can then take on the magnetic field of the North to South poles of the earth depending on the brick's orientation at the time. So you _could_ have magnetized bricks.

Iron oxide is the magnetic coating on open-reel tapes, oxide cassettes,
8-track cartridges, VHS and Beta video cassettes etc.

A side note to the power line stuff, I talked to a Service Enginner
for one of the
E microscope companies many years ago. We talked about power line
problems, I was
returning from a Service call on a older style X-Ray system (non HF
inverter) on 2 phase ac, where the problem was a major inbalance between
the 2 sides of the incoming line. He mentioned he had recently worked on
a problem where the neutral leg for a major run through the Microscope
area had opened up, resulting in the conduit was carrying almost 400
amps. The resultant magnetic field to caused him to almost pull his hair
out until he did a magnetic survey of the room and found this huge field
originating from the electrical run. The Maint. people were totaly
unaware that the neutral line had opened up. When they repaired the bad
neutral run, the magnetic field disappeared, and the microscope worked fine.

Very true! It's well known that nuclear power plants, for example,
produce too much neutron-induced phase jitter in the 60Hz power.
Coal-fired steam is far superior, to anyone with a discerning ear.
Hydro power is tolerable, but it definitely has reduced mid-range brisance.
(It's important that the dam be located *east* of its reservoir
to reduce coriolis torqe effects! And the dam must be made of audiophile-
quality concrete.)

Doug; I cry every time I think of the old high impedance speakers I trashed as a kid just to get the horse shoe magnet. If you really want a 2000 ohm speaker, head for an antique dealer and start looking. Take your ohmmeter with you as the DC resistance will be about the same. The Horn speaker was and still is just a single high impedance earphone driver unit. But as someone else stated, get a set of high impedance earphones (Brandes was one manufacturer, again usually at the antique dealer) and use these. Good luck and have fun. Keith, VE3JKC.

Well, judging by the way the power cords are in the U.S., the blue wire
is neutral and the brown wire is hot. And that is counterintuitive to
me. If you don't believe that, then chop off the end PS of an IEC power
cable for a PC, and strip the wire ends and make a continuity check and
confirm what I said. Blue = neutral, brown = hot.

Doug.
I've built "100s" of these and on many occasions have used the telephone earpiece from old BT 706 type telephones. (Bell, type with a dial, classic 60s and 70s shape.)
I've found them to work everywhere from very faint to quite loud.
A rolled up card "megaphone" has then converted the earphone into a speaker with good results.
I've even gone as far as to make a swan necked speaker using newspaper and white glue.
A book called "The voice of the crystal" by H. Peter Friedrichs (I got mine from Lindsay publications) shows how to make high impedence headphones from guitar pickups and shoe polish tins and crystal headphones from piezo lighters.
If you need anything specific, mail me off list. I am friendly with Gerry Wells of the Vintage Wireless & TV Museum in Dulwich, London and he may have what you need.
Cheers.
Mark H.

If you can't find anything elsewhere, see if your local
Radio Shack has a crystal radio kit for sale. It should come
with a high impedance earphone.

Scary thought. Nowadays, those big breakers in the electrical panels
have GFCI so it would seem that such an anomaly would have tripped a
decent breaker.

Only single phase. With 2 or 3 phase driving anything but motors it's real easy to get unbalanced. This is mostly feeder lines that cause the problems. But I've deal with 2 firms where the local 3 phase 4 or so KV feeders were unblanced enough to cause monitor vibrations at 60Hz. Power company said "Sorry, were re-routing for a while to move some cables. Should be done in 6 months or so." These were for 19" CAD stations. Ugh.

antique electronic supply carries modern 2k phones and play things of the past also carries many older types of high impedance phones. Gary at ptop may also have some hign impedance horn drivers.

look them up on a search engine, both have web pages

also unless you are trying to build a pure crystal set I would add a stage of audio amplication even with the high impedance phones.

The SCR has no part number, but one that is capable of 25 amps anode current should work. The pot is 100 ohms, the resistor connected to the wiper of the pot is 47 ohms, and the gate of the SCR has 150 ohms tied to common.

This crowbar circuit does not blow a fuse as some simpler designs do, but relies on a current limiter downstream of the pass transistors to pick up a relay and remove voltage from the emitters of the transistors. If the current limiter is not working, I would not worry about the crowbar circuit, if it crowbars it will likely smoke something, like the transformer or the pass transistors.

Is this tantamount to the fact that the current output
of the xtal set is limited and that if R is too low the 'theoretical'
current
per ohm's law (i=V/R) exceeds the capacity of the xtal set?
If that is the case (and my guess is that I'm way off base here),
then a resistor in series with speaker should work, right.

Thanks,
Doug

You seem to be forgetting Kerchoffs current law. Your currents must
balance, unless you've got some leakage to ground somewhere. While your
loads and load currents may be unbalanced, the total current through the
cable should cancel out.

Here in the US, typical 230V (3-wire) power wiring feeding cooking
ranges, electric dryers, air conditioners, etc. is usually NOT
balanced. If you think about the differing voltage loads present is
these appliances you'll realize why, plus understand why 3-wires are
needed rather than simply 2.

Perhaps is time for someone to observe that there are different types
of Iron Oxide, magnetic and non-magnetic. I'm not a chemist, but I
believe one is Fe2O3 and the other Fe3O4 (in minerals, Hematite and
Magnetite).

Hematite is known for its blood red color, is non-magnetic, and often
used as a pigment for coloring bricks and concrete.

Magnetite varies in color from gray to shades of red, is magnetic, and
often used in applications because of its magnetic properties.

While the two hot sides may not be balanced, the total current sum for all the conductors in the cable is zero. Anything other than that indicates a severe safety problem. It the two sides are unbalanced, the difference current will be carried by the neutral conductor. If the two sides are balanced, there will be no current in the neutral.

>large but not small impedance speaker?

In order to transfer the maximum amount of power (P=I x V), the load impedance should be as large as the internal source resistance. If the load resistance is less than that, the source is capable of supplying slightly more current as in the optimum case, but the available voltage drops quite drastically, thus the available power (P=I x V) drops also drastically. If the load resistance is too high, the voltage will slightly increase, but the load can not use all available current, so the power into the load drops drastically.

Trying to figure out what the source impedance for a crystal set is quite hard in the general case, but using some assumptions, some ballpark numbers can be obtained. Assuming this is a medium wave crystal set (550-1600 kHz) and the antenna is 10 m or less. A crystal set usually has a single tuned LC circuit in front of the detector and the maximum capacitance of a typical variable capacitor C would be 500 pF. If we are looking at the middle of the band at 1000 kHz, the required capacitance would be about 150 pF. This would give a capacitive reactance (X = 1 / (2 x pi x f x C)) of about 1000 ohms.

It might look as if a load of about 1000 ohms would be sufficient, but since the antenna is much less than a quarter of a wavelength, it is not resonant and it behaves like a 15-30 pF capacitor in series with the signal source. At 1 MHz the 15-30 pF capacitance represents a reactance of 10000 to 5000 ohms, thus the load should be somewhere in this range.

At resonance (when the inductive reactance of the coil and the capacitive reactance are equal, but they have opposite signs) a parallel LC circuit impedance is _much_ larger than the capacitive reactance alone. Typical values are 100 times larger.

This Q value will also control the selectivity of the receiver. The bandwidth is defined by BW = f / Q, so in this case if Q = 10, the bandwidth would be 1000 kHz / 10 or 100 kHz and with Q=100, the bandwidth would be 10 kHz, which would be quite optimal for listening

to AM transmissions.

When Q is 100, the reactance at resonance must be 100 times of the capacitive reactance of its own, so the reactance would be 100000 ohms. This is also the optimum load impedance.

>Finally, where can I obtain a 2000 ohm speaker?

I guess that 2000 ohms has been simply been specified as it is the highest headphone impedance that is commonly available today. But according to the previous calculations, the load impedance should be much grater than 2000 ohms for optimum performance.

Use an audio transformer to convert the high impedance to a low value and use ordinary headphones. If you can find an old tube amplifier output transformer, it might have a 5000 ohm primary impedance for driving a 4 ohm speaker. If you connect 32 ohm headphones to the transformer secondary (originally intended for 4 ohms i.e. 8 times less) the primary side will load the crystal by 8 x 5000 ohms or 20000 ohms, which is much better.

The 20000 ohm load would load the tuned circuit so the Q will drop to 20, thus the bandwidth would be 50 kHz, which would still be usable, if there is only one strong local station at that end of the dial.

If you can find 600 ohm headphones, e.g. from an old electromechanical telephone and using the output transformer from an old tube amplifier would give a quite optimum load impedance.

>then a resistor in series with speaker should work, right.

'Fraid not. Yes, you won't overload the set's output, but you won't be generating any useful sound output from it, either. Your set needs to 'see' an impedance of 2000 ohms presented to it. Your suggestion means that you present it with say an 8 ohm speaker in series with a 1992 ohm resistor (yes I know they don't make 'em but you know what I'm getting at). All well and good so far as the set is concerned. However, you're going to uselessly dissipate the vast majority of the available output power in the resistor at the ratio of 1992:8 which will still leave you with diddly-squat volume. The idea is to dissipate all the available output power into a *useful* load - and a resistor just ain't one! In the *true* spirit of vintage radio, I'm afraid there's no alternative to hi-impedance speaker/phones.

Use a small 8 ohm to 2000 ohm or so transformer - probably available from Radio Shack. Unless the crystal set has some sort of amplifier I expect that you will not get much volume from the speaker. The volume level is typically about right for a 2000 ohm or higher impedance headset.

Radio Shack as a couple of different battery operated, amplified mono speakers that would probably work well and give a much higher level output.

There's also an outfit on the web called Antique Electronic Supply that has some very high impedance crystal type headsets and other supplies specifically for crystal sets.

886. Which ferrite toroid cores should I buy for an SWR/wattmeter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-01 16:13:23 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0302010813.7168dd42@posting.google.com>
Source record: 38088
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna,alt.engineering.electrical,sci.electronics.design,sci.electronics.components

I am working on a better 1.6MHz-30MHz SWR/wattmeter for a graduate school independent study project. It will be able to handle power levels as high as 200W (thus comfortably handle the full 100W) and power levels as low as a small fraction of a watt.

As you know, SWR meters use transformers as sensors to sample the load current and voltage. Type 43 material looked like the best choice. Most of the SWR meter designs I have seen use type 43 toroids (FT50-43), and http://www.bytemark.com/products/fermgprp.htm gives this material a frequency range of 1-50MHz.

I will be placing my order on Monday, and I am leaning towards FT50-43, since that seems to be the consensus of others who have built SWRmeters.

My three questions:
1. Should I use type 43 or type 61 material?
2. What size toroid should I use?

Regarding question 1:
I was all set to order several type 43 toroidal cores from Palomar Engineers only to find that they recommend type 61 at http://www.palomar-engineers.com/Ferrite_Cores/ferrite_cores.html. According to the Palomar web site, transformers should use type 43 material is for .01-10 MHz but type 61 material for .2-100 MHz. Bytemark lists the wide band frequency range of type 61 material as 10 to
200 MHz

Who is right? Palomar recommends type 61 while Bytemark and the consensus of homebrewers recommend type 43. Under what circumstances is type 61 better, and under what circumstances is type 43 better?

Regarding question 2:

I estimate that in the worst case scenarios (100-200W and a short circuit or open circuit for a load), the RF transformers may be subject up to 1-2 watts. This doesn't sound like much, but my Radio Shack resistors can only handle .5 watts.

I will be using either type 43 or type 61 ferrite material. I noticed that most cores used in other SWR meter designs are size FT-50, which is .50 in. outer diameter, .28 in. inner diameter, and .188 in. thickness. Larger cores take up more space and cost more, but I believe they can also handle more power. (Correct me if I am wrong.)

Would I need the F-50A size core (.25 in. thick) or F-50B (.50 in. thick)? Is there any reason I should use a larger core? A smaller core?

Would using a larger (or smaller) core narrow the bandwidth or make it less sensitive? Remember: I want my device to work from 1.6 MHz to 30 MHz and at power levels as low as a fraction of a watt.

Also, I have heard that Amidon has a formula for estimating the maximum power a transformer can handle without heating up excessively. Can anyone have a link to this?

> 1.5MHz, 1 V/us and under 90 cents quantity 1k, seems a nice
> jellybean candidate to me. Hmm, what about second sources?

Actually, perhaps I should take the jellybean bit back. The
LMC6482, like all rail-to-rail output opamps, suffers from
high open-loop output impedance, which makes it harder to use
with capacitive loads.

For example, I'm just now analyzing a opamp-controlled current
source with a MJH11021 250V 15A PNP darlington transistor, and
the '6482 is making the circuit very hard to compensate without
completely destroying its high-frequency response. (Adding a
1k5 load to the '6482 didn't help. Using an IRF9640 p-channel
MOSFET instead of the BJT stopped the ringing, but reduced the
response by 10x, due to the FET's much higher capacitance.)

Replacing the '6482 with an LF411 (I needed input operation to
the + rail, which was why I chose the '6482 in the first place)
solved the problem, allowing response to 100kHz. This can be
attributed to the LF411's low ~ 40-ohm open-loop Zout. Most
other BJT opamps would likely also prove able to drive my big
BJT, e.g., an OP27 worked fine (after adding a 2nd supply).
But I tried a 741, just for fun, and it oscillated madly. :>)

Thanks,
- Win

You might find more information at http://www.amidoncorp.com/

As far as the different materials, why not try it with both types?
Then you can include the data as part of your project to show which type
is better, and why.

Other than the electrical characteristics, there is the simple mechanics of getting the required number of turns on the core. A smaller unit is also easier to mount.

iirc, 43 mix is about 8 times more permeable than 61 and the formula is

turns = 1000 * sqrt(mH / A) where A is the inductance index which is proportional to the permeability for a given size.

Fewer turns, smaller size, possibly less distributed capacitance.

Then there is the junkbox factor -- the person who designed it had a bunch of T-50-43 cores at hand.

>including combinations of cells that may not be what ICOM had envisioned.

I spent 11 years at Icom, funny how being gone for almost two years
what one forgets.

The rapid charge BP series ie: BP-5, BP-7, BP-8 all are controlled by
temperature. If you look between the cells you will see a device that
appears to be a " fuse " it is actually a thermo cutout. Once these
batteries reach a predetermined temperature the cutout opens and the
charge stops. I don't have any information as to the temperature that
cutout operates at. A flip-flop within the charger is set and it takes
physically removing the battery and reinserting it to restart the
charge cycle or a power off / on cycle will do it so.

The BC-35 has no way of measuring the battery voltage to control the
charging. .

It seems to me the most rapid charge is about 600 mA I forget what the
center switch charge rate is though. The trickle charge rate was 25
Ma. On the BP-4 battery pack you will not find a charge rate plate.
You can determine which switch is pressed as that position will not
have the hole in the plate. Icom used to have a service manual for the
BC-35, it was in the back of the M-5 service manual.When I was there I
photocopied it many times and sent it out or faxed it free of charge.
It was only about 5 to 7 pages as I remember.

The BP-3 is trickle charge only, charges at 25 mA and does not shut
off when it reaches full charge. It has no thermo cutout.

Hope some of this helps you.

This is an adequate short hand for the veteran, but is too vague for
your needs. You would be far more informed if you found the same spec
as a graph across frequency, especially with overlays of the spectrum
of core formulations. My Amidon references do this in spades.

>

Buy $30 worth of an assortment of types (even beyond these two) and
core sizes (or binocular style). It is a cheap and vastly more
educating experience to settle down with an array of candidates and
ask them all one question, while measuring a variety of key
characteristics. Then change the something.... Run this loop a dozen
times and there will be damn few questions remaining.

A graph would make this a slam dunk. Spend some effort in finding
that.

>

On a weight basis, how many ï¿½W resistors are needed to equal the
weight of your core? This may seem absurd, but it is a first cut
approximation considering bulk alone. The amount of sense, beyond
that, is incumbent upon how like the two are. They aren't. So I
would offer that this is a lower limit because the cores have a
uniform composition.

Again, if you go hog wild in ordering cores; you can perform your own
stress test to destruction as part of your analysis (last test
presumably, unless you want to test the efficacy of epoxied ferrite
shards).

My guess is about two Watts for the usual core applied to RG-58
current BalUns. I would suppose 5W would be destructive, but would
love to hear from your results.

You don't want power in the core at all. You are probably over sizing
this. If you simply cracked open your rig and looked at its SWR
bridge, you would then see a design tolerant to the same criteria
you've put to your project - n'est pas?

Hi Jason,

Core size is material only for dimensional demands of the lines passing through its center. The point of most BalUn construction and bridge design is found in isolation. Large is good in that respect because it serves to separate. However, dimension, as a function of wavelength demands a conflicting requirement for shortness of lines.

As for:
>I am working on a better 1.6MHz-30MHz SWR/wattmeter
Better? What are you bringing to the table or is this a quest for enlightenment? Better is an advertising term, not an engineering specification.

I'm not sure what you mean by balanced. With the '2-phase' 230VAC lines in the U.S., the current going out of one line is of the opposite phase of the current coming in from the other line, so the current is balanced assuming the loads are equal. And if the center tap of the transformer is really a center tap, then the voltages are equal, ignoring the voltage drops, which should be equal if the currents in both legs are equal. This is for a standard residential neighborhood where there is no 3-phase power.

http://stevenet.freehosting.net/icom/ has a "2 component Icom Clone & CI-V Cable", which is perhaps the simplest I've seen of these. I plan to connect an ICOM R2 to my computer. Questions: does one connect all the "gnd"'s and the little "brush feet" ground symbols all together? Replace the jack with a mono one--ok, I can handle that. It is a simple circut but still safe for the few things one can do with the R2? Uh oh, what about the 5 volts, wasn't that supposed to come from one of the D9 pins?

I just go into a store with drawers full of that stuff and ask the young man to solder it together for me? (Or take it home and, hark, do it myself.) Thus I will save big bucks over the Parnass-suggested http://cloningsoftware.com/addtocart.cfm?product=CT-29A&price=25& easy way out?

Hopelessly wrong !

Things are already more than weak enough without connecting 100K-ohm
resistors in series with 8-ohm LOUDspeakers.

In this case it's probably worth adding that the resistor in series
with the loudspeaker will provide the high impedance load. But
the problem is that the resistor and the loudspeaker are a voltage
divider, so whatever signal is at the top of the resistor is divided
by the divider. Considering that two resistors of the same value divide
the signal by half, a 100K resistor in series with an 8 ohm speaker
would be close enough to infinite that the difference wouldn't matter.
In other words, you won't hear anything.

Not necessarily. The problem is that a 100K-ohm speaker will likely
require a much higher voltage (which the crystal set cannot provide)
in order to drive the speaker to same level as a 2K-ohm speaker. Too
low an impedance and the source can't provide enough current. Too high
and the source can't provide enough voltage. The maximum power
transfer to the speaker occurs when the source and load are properly
matched.
```

Excuse me for butting in, but I have to ask a question. When I was in school, "two phase" required four (4) wires. Two for each phase. If you tried to run two phases on two wires, you would get either nothing (as one would be hitting +100 v at the same time as the other phase was hitting -100 v - sum = zero or a short circuit thus sucking your current 100% and burning out all of your wiring).

Three phase uses three wires, one for each phase (and can use a fourth if you are running what is known as "wye" instead of "delta").

"Typical 230V (3-wire)" as found in homes is single phase with two "hot wires" and a neutral. Each conductor is 110V with respect to the neutral. And yes, there can be a very large imbalance between the two hot conductors when you have a lot of 110V appliances (refrigerators, freezers, space heaters, window air conditioners, etc) on one leg and nothing but, say lighting, on the other. (And you should see the fun in a house when the neutral opens and just the two hot lines are doing the feeding. Talk about light bulbs getting extra bright!!)

Three phase delta uses three wires with one phase on each. Sometimes a center-tap is placed on one of the transformers supplying the 3-phase thus giving you a 110V to supply between ground and either of the two phases either side to the center tap (assuming 3-phase 220V). But the voltage between any two phases will be the sum of the phase you are measuring and the other phases, thus giving us various voltages from 177v to 208v etc.

Back to the point, "2-phase" is quite rare, in fact, I don't believe I've ever seen it in real life in over forty years in the business.

bob

Source record: 38003
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna,alt.engineering.electrical,sci.electronics.design,sci.electronics.components

With any of the ferrites of reasonable permeability, coupling isn't a problem in a transformer -- you'll get very close to a unity coefficient of coupling with any of them. So the issues are:

1. You need to have adequate winding impedance. That is, the impedance of a winding should be at least several times the impedance of the circuit it's connected across. Unless power dissipation is a problem (see #2, below), it doesn't matter what the angle of the impedance is. A resistive, as opposed to reactive, impedance is often more desirable because it stays relatively constant over a wide range of frequency.

2. Heating. The power the core dissipates due to each winding is approximately winding I^2 * R, where R is the resistive part of the winding impedance, and I is the signal current in the winding. You can keep this product in bounds by making R high. The heading will of course be less for larger cores. I've found that hysteresis or other amplitude-related loss isn't a concern for this sort of application. But you'd undoubtedly impress your professor by showing that you considered this, and the calculations you used to arrive at your conclusion.

The frequency ranges given for ferrites are often based on the frequency range over which their impedance is primarily reactive, i.e., the range over which they make decent inductors or tuned circuit elements. These aren't the criteria that are important for broad band transformers, however. The main properties you have to consider are the ones impacting the two considerations above. Ferrites like type 61 have lower R for a given impedance, but you might not be able to get enough impedance over the frequency range, especially when resonance effects are considered. Type 43, on the other hand, might have dissipation problems at 200 watts. Welcome to engineering!

A graduate student should be able to calculate the necessary value of winding impedance based on the design requirements. You can find the impedances of cores of various sizes and materials at the Fair-Rite web site. Estimation of temperature rise based on physical size and mounting is also something a grad student should be able to handle, at least approximately. (A simple lab test to show the validity of the calculations or approximations would be a plus.) If you submitted your work to me as evidence of your ability when interviewing for an engineering job, I'd put a lot of weight on how you came to make the choices you did. Perhaps your professors use different criterion for judging work, however.

You hinted at it enough.

Each bulb is wired to a different phase of the three phases. As long
as they are equal in brightness, the three phases are balanced. If
there is an imbalance, such as from a broken connection, one might be
out or one might be very bright. This would alert someone to do a
check of the wiring.

although I don't doubt for a moment that it's possible to make up your own cable, risking damage to an expensive scanner is a danger I can do without! That's why I bought the cable for $25 + 5 shipping, and consider it worth the money! Having one has made my R3 radio so much easier to use!

Common household power is 240V split phase, where each side is 120V to neutral. One hot side is 180 degrees out of phase from the other. If loads are equal, the current goes from one hot wire through the loads to the other, with no current in the neutral. If the loads are not equal, there will be a difference current, returned by the neutral.

> assuming the loads are equal.

My point was simply that most of the common 230V appliciance used here
in the US do not impose equal loads on each phase of the circuit. The
difference current is returned by the neutal, hence the need for
3-wires.

The perfect example is an electric clothes dryer. Its heating element
is driven by 230V and and in itself imposes a perfectly balanced load
on the line. On the other hand, the electric motor that rotates the
drum in the dryer operates on 115V, draws current from only one phase
of the 230V supply, and uses the neutral for its return.

That's simply what I mean't by an unbalanced load that results in
unequal current from both phases of the supply. It's not an uncommon
situation since many air conditioners an other 230V household
appliance operate in the same way.

Of course there are exceptions. Normally electric hot water heaters
operate on 230V, and do present a balanced load. If you throw in a
115V electric motor to drive a heating schedule timer, even their load
becomes slighly unbalanced.

When the current draw from one side of line to its return is unequal,
the load is said to be unbalanced. (Not that it makes a great deal of
diffence in most cases.) The load creating the unbalance simply
employs the neutal line for its return path, hence the summation of
current flow though the feeder cable, except when a ground fault
occurs, is zero. (However, this doesn't even begin to suggest that the
EMF from the cable is zero, although that EMF is minimized if the
cable consists of a 3-wire twisted configuration, which of course is

not very common.)

Still, load balance is a only matter of serious consideration WRT the main power feed to the facility, but in the case of a private home balancing the load between the two-phase 230V supply is generally not a critical issue. On residential installation most competent electrical contractors will try to assure that the 115V circuits are equally distributed between each of the two phases of the feeder line. However, they do often forget to consider the load imbalance created by 230V appliances, as I've described above, plus they have no concept of which brances of the distribution circuits will become simultaneously heavily loaded. They simply put half of the 15 amp breakers on one phase of the line, the remainder on the other, and hope for the best!

On an industrial scale balance is serious, because a grossly unbalanced load could exceed the capacity of one-half the secondary windings on a pole mounted distribution transformer and result in its premature failure.

I am of course entirely neglecting the EMF or EMI consequence of lines driving unbalanced loads which led us down this path originally. That's simply because the venues where EMF could be of possible concern are usually fed by 115V branch circuits, which by definition are balanced (since thre is only one phase, one hot wire and one return). EMF becomes a much greater consideration in facilities which share specialized equipment driven by 230V single phase (actually bi-phase) and/or 208V through 480V 3-phase supply lines. Here the ramifications of an unbalanced load cannot be ignored.

Verbose as this post turned out to be, I hope it is helpful.

Source record: 38013

There are at least a couple of advantages in running the VFO at a
higher frequency and dividing down:

1) the percentage bandwidth that the VFO must tune (at its fundamental)
is much smaller.
2) dividing down will reduce phase noise by the ratio of the division

> headset.
=======
If you really want to use a transformer with impedance ratio of 8 : (2000 or more) you can use any small transformer with a winding ratio of sqrt 8 : sqrt (2000 or more) = 1: 17 or more.

Testing ,with a low voltage power transformer 2 resistors and a DVM.
Get approx 100 - 200 mV AC 50/60 Hz from power transformer and resistive voltage divider and connect transformer under test, which can be any small transformer ,whether meant for power ,or audio. Most junk boxes have these.
Measure input of transformer under test as well as output . If voltage ratio is 1:17 or more (or 17 or more :1 depending on how you connect transformer ,the transformer when (correctly) connected to speaker or head phone and crystal set will present an acceptable load to the crystal set.

If you use low cost computer headphones with a nominal impedance of 32 Ohms , the transformer winding ratio required becomes sqrt 32 : sqrt (2000 or more) = 1 : 8 or more .
This will allow you to use a small low voltage AC. transformer of say 115 to 12 V or similar ratio. It would be even better to use the lowest available low voltage tap ,say 3 V .
In that case the voltage ratio is 3 : 115 = approx 1 : 40 hence impedance ratio would be 1: 1600. So, with 32 Ohms headphones connected the crystal set would be presented with an impedance of 32*1600 = more than 50000 Ohms.
With a crystal set producing veeeeery little power ,using headphones seems most appropriate.

An "inverse shunt" would be an amplifier. You want 200uA amplified 2.8X to
560uA.
A simple and cheap alternative to adding the amplifier stage would be to use
a $10 200mV digital panel meter with a 1K resistor shunted across the
input.

==========

Yes, obtain a meter which has a sensistivity of 200uA or better. Meters as sensitive as 50uA FSD are probably available. Make sure the movement is damped against oscillation.

Or invent a meter shunt which has a negative resistance and apply for a patent without delay. Somebody might beat you to it.

920. Re: mixer and tank question

Newsgroup: rec.radio.amateur.homebrew

Source record: 38023

In short: NO!
It will degrade the performance of the mixer as energy will bounce
back into the mixer and cause distortion.

Use a diplexer filter to wide-band terminate the mixer to ensure no
reflected power.

You still need to have a filter at the input!

That's a reasonable way to put it.

Adding a resistor in series would keep you from drawing too much
current from the set, but then you only get a fraction of the total
available power into the speaker; the rest is wasted in the resistor.
The goal is to get it all into the speaker.

OTOH, I have no idea where one might find a 2000 ohm speaker. 2000 ohm
headphones used to be available and this was what was commonly used in
crystal sets. Your best bet for finding such a pair today is probably
at a swap meet.

If you're really interested in doing this a better way, you should study the Bird model 43 wattmeter. It uses NO ferrites and works well above a kilowatt. It uses no obvious transformer, although the transformer concept is there.

Once you understand how these work you would never again consider any kind of explicit transformer.

Not so oddball at all. I've seen those connectors, and there's
nothing really exotic about them. Take a look at http://www.amp.com, and
look for the 'CPC' (Circular Plastic Connector) series. Bet you could
even talk them out of a sample if you just need one or two.

Good hunting.

930. Re: mixer and tank question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-03 15:38:51 UTC
From: Richard Hosking <richardh@iinet.net.au>
Message-ID: <3e3daf51$0$406@echo-01.iinet.net.au>
Source record: 38026

The mixer's performance and input impedance will depend on what load it is looking into. It is best for most mixers to look into a broadband resistive load so that all the likely output products are terminated in a predictable fashion. A tuned circuit at the output will obviously be reactive at most frequencies. A broadband resistive load could be a resistive pad (easy but lossy) or a diplexer (better but harder to do). Interestingly I think there is a situation where your question does apply. The Tayloe mixer acts like a (very sharp) tuned circuit at the LO frequency with a low impedance around the LO at the input and this impedance rising rapidly at offsets away from the carrier. This mixer configuration is 4 bus switches (or presumably any electronic switch) with the LO in a 4 phase configuration with a 1:3 duty cycle. The input is commoned and the outputs feed an audio low pass filter (simply a capacitor in the original circuit). Thus the circuit is a direct conversion system and can be used to feed an audio phase shift system for SSB reception. I would be intereested if anyone has ideas on the theoretical analysis of this configuration.

Hello all,
I was just given the above counter. After repairing the power switch (was hardwired due to broken switch) I powered it up. Display lights up OK and seems to work but it does not display any frequency at the input. Used my other counter and generator, no matter what frequency I put in it didn't show anything. Anyone have a manual or an online site I can look at with a schematic? Or a place I can get a copy of a service manual? Thanks in advance.

Just tell them that the sun is a large source of all types of
radiation, and in fact is powered by a nuclear reaction which is not
shielded.

Then they will hide at the bottom of a mineshaft to protect
themselves, and leaving you alone.

(Once they are at the bottom of the mineshaft, you can drop down a
note warning them about radon gas.)

I've used a couple simple 1.5V oscillator circuits for some time that seem to work reliably. In fact, both work down to below a volt with silicon transistors. One is a simple 2 transistor, 4 resistor, 2 capacitor astable flipflop. You can put a little audio transformer in series with one of the collector load resistors, adjusting the resistor to get the volume you want, to feed a speaker. The other is a "blocking oscillator" which uses a transformer with center tapped primary to get feedback. You can see an example of it in a circuit tracer probe at http://www.techlib.com/electronics/rbeeper.htm. You only need Q4, R6, R7, C1, T1, the speaker, and a resistor from base off to a key-down signal. It's possible to play with it to make wider pulses so the tone is a little softer. You should also be able to make a phase shift oscillator which produces something close to a sinewave, using a single transistor and a few Rs and Cs. It may be possible to drive a small speaker directly by putting it in the emitter lead of the transistor. You'll also find some variations on another theme for a relaxation oscillator that runs best on a bit higher voltage, in the www.techlib.com archives.

Cheers,
Tom

936. TiCK-4 Keyer

Source record: 38044

Someone posted a similar query to QRP-L a few weeks back, and the response from one of the principals of Embedded Research was yes, they are still around, and yes, they still have the TiCK-4. However, they are somewhat slow in responding to orders, even slower responding to emails. It isn't their main source of income and like so many amateur run businesses, they are finding real life interfering with their hobby.

There are several similar kits out there, the Island Keyer comes to mind, but there are a few others. Each has a feature set that is a superset of the TiCK, and generally they tend to cost a few more dollars.

Personally, I finally decided it was better to roll my own. It's not all that tough to do a keyer with a PIC, and then you can get exactly what you want. Until I used my K1 for a while I hadn't realized all the things I didn't like about the TiCK. By writing my own, I could get what I wanted, and I found that there were some added advantages when I was homebrewing a rig.

If you are going to FDIM, I'm sure they will be there, or someone will be selling their stuff. In fact, you might check Morse Express, they may have TiCKs and if not, I'm pretty sure they will have something similar. I just took a peek, they have several (but not the TiCK) ...

3 phase is quite common in industry. Also, all the power generated is 3
phase, with home power coming from one phase. The local hydro will try to
balance the number of homes in a neighbourhood over the 3 phases.

943. Source for 70 MHz IF filter

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-04 03:44:04 UTC
From: Bill Beal <bbeal@hilcozap.net>
Message-ID: <8GG%9.9$s7.14144@news.randori.com>
Source record: 38046

I am looking at building a simple all-band receiver. After going through a lot of the litature, I belive a first IF around 70 MHz would be a good candidate with a second conversion to a more resonable IF frequency (455 KHz to a few MHz). I have looked but not found a source for crystal filters at around 70 MHz. Preferably 8 poles with about a 15 KHz bandwidth is my desired goal. Does anybody sell these in small quantities (lots of 1) at a reasonable price (not the price of a top notch IF filter as for some of the commercial rigs)?

Bill, WD5HHH

I have a couple HP counters, I've repaired a few 5328a's too (not 5382, however) -- make sure that the "Internal/External" source in the back is switched on Internal. You can also check to see whether the oscillator is humming by looking at the output in the rear.

Depends on where you are and what sort of service you request from your powerco. At work, the building feed is something like 13 KVAC 3-phase, my computer room UPS eats 480 VAC 3-phase, and the UPS output is 220 VAC 3-phase, all measured phase-to-neutral. But my house is 110 VAC "2-phase", which really is 220 VAC across the hot leads, with a center-tap neutral. The central heat, stove, and air conditioner are 220 VAC, and everything else is 10 VAC.

I could get a 220 or 480 VAC 3-phase service drop from the powerco if I were willing to pay for it, but I don't have any use for it.

Yes, quite common in industrial settings, especially heavy industry.
Bring in a bunch of machine tools, welding equipment, and other
serious equipment and all of a sudden that doesn't look like a lot of
power.

Some people who do welding at home in serious way get the heavy duty
power installed, but it can cost as much as getting the rest of your
home electric service installed.

Happy trails,

> accomplish it reliably.

Well, speaking as one who resells mil-spec connectors as part of my
side business, I can tell you that 'reasonable' is very much a relative
term in the world of crimpers.

To my eyes, $100 or so does not seem at all unreasonable for a
good-quality tool, such as one that does a hex crimp, to work with any of
Anderson Power's connectors. Since there is some standardization in the
world of large-gauge wire lugs, it seems to me that same tool would be
useful for other electrical jobs as well.

I will grant, though, that the heavy crimpers are not generally
needed until you get down below about #12 wire. The primary leads in the
van's distribution system are #4 aircraft-grade, which means lots and
lots of strands (the stuff stops just shy of Litz wire).

Soldering was most definitely not an option in this case (I
probably would have needed a small torch), both in terms of stressing the
contact itself and in terms of the joint being unable to flex with the
vibrations found in any mobile environment.

Anyway... If you'd like some perspective, the three standard
crimping tool frames used for most of the cylindrical mil-spec connector
contacts, and for many of the coaxial connectors as well, range from
$200-$300. The pneumatic-powered versions of those same tools can easily
run from $700-$1,000+.

You also need the correct contact positioner for the specific
contact type, or range of types, that you're working with. They run
around $75.00 each, and there are literally hundreds of different types.

Insertion and extraction tools run from $20-$50 per. You don't
really need insert tools for any contact at size 16 and up, but they are
a must for the smaller contacts (size 20, 22, and 22D).

I hope that helps clear up why the 'ratchet' or 'hex-crimp' tools
are more expensive than the cheapies. ;-)

> Bill, WD5HHH
>
I don't know about specs, but an obvious (and cheap) source of
roofing filters would be old cellphones. The older the better
since the parts are more recognizable, and bigger. The four or
five I've taken apart, having bought them for a few dollars at
garage or rummage sales, haven't shown much of a pattern on
the filters, other than that they are all above 30MHz. From memory,
one was around 45Mhz, another in the 70MHz range, and another in
the 80MHz range. If you could get two identical phones, you could
cascade the filters if necessary to get a better shape factor.

The phones I've bought all had crystals to convert from this
IF down to 455KHz.

I once brought home a Motorola VHF receiver (or was it a transceiver?)
board that had a couple of three pin crystal filters in the 45MHz
range.

Other than that, or finding some by themselves at a hamfest,
the most obvious place would be transceiver manufacturers.
But considering the high cost of optional filters, I suspect
these would be really expensive, even if you could buy one.

I seem to recall seeing a KVG ad somewhere, maybe QEX, some
years back that listed a roofing filter. But it was at least
a hundred dollars.

I think there's virtually no market for single quantity filters,
so nobody is going to bother carrying them. Obviously they
are manufacturered, but getting one would be a problem.
Ten or fifteen years ago, I noticed somewhere that Fox,
that manufactures those cheap TTL oscillators in a can, supposedly
also made crystal filters. I mailed off for a catalog, and
must have asked about prices, since I got the catalog with
plenty details on various roofing filters, but the cover

letter said something about how their prices were proprietary.
Well, if I couldn't even get an idea of the price range, there
basically wasn't any sense in pursuing the filters any further.

i want to build a W8NX antenna,
But i found some different versions of it.
At w4rnl his site are different lenghts as the one in the ARRL antenna handbook.

could anyone give me the dimensions (links Photo's) of a W8NX antenna ?
there could also be a qoustion left about the best way of feeding the traps (high Z , low Z).
What is best for working all bands fed with just 75 Ohm coax ?
Or could it be better being feed with 50Ohms and matched with a 1:2 Balun?

The Z of most of the bands are higher than 103 Ohm.

anyway if someone could help this Dutch radio amateur a bit further...he is almost with one leg at the stairs to th e roof :-)

Source record: 37906

I remember ordering the AM crystal filter for my KWM380. I contacted Piezo Technology, and they sold me one for 245 dollars. If I wasn't working for Collins at the time, they told me that they wouldn't even bother making it up.
Like Michael said, a good source of those filters are in old cell phones. Some of the 10 year old Motorola equipment used crystal filters at two frequencies; these were 45MHz and 45.1MHz. They also have the required crystal to downconvert to 455kHz. If you used a pair of 2-pole units, with an amplifier embeded in between them, you should get around 80dB of (2 X 2nd I.F) rejection, provided you use a diplexer after the 1st mixer. What I have been using has been a series L, shunt C network to match the mixer to the 1st crystal filter, and on the other leg, a parallel tuned circuit, with Xc and Xl approximately 50 Ohm through a 50 Ohm resistor, to ground. This circuit has a bandwidth of approximately 15kHz.

I don't consider any prices associated with "mil-spec" to be
anything other than an anomoly to be discarded without before it
contaminates the rest of the data. If the prices are good, great,
if they aren't, oh well. There is too much random variability in
the prices commanded by "mil-spec" to have any relation to reality.

I don't recall an easy source of 70 Mhz filters, but I have seen 45 MHz filters on Digikey for something like $18 each. Not bad....

Although it would require better selectivity on the front end of the radio. However, to get strong signal handling, you are probably going to use front end filters anyway.

Here is the Digikey part number:

410-1004-1-ND

It is 14 KHz wide.

Second that motion. Wasted a lot of time over the weekend trying to control an LMC662. Had 62 ohms in series with its output, which consisted effectively of a 13k resistor in parallel with probably 50pF of cable and whatnot. It sat there oscillating like a madman, at about 600kHz, 0.5V (a single 9v supply provided by a battery). Caps in the feedback loop did little or nothing up to the point where even my audio-band response was compromised. It finally worked, moderately well, to put 620R in series with the output. But even then it still rings a bit... For the final design of the thing I'm working on I'll use LMC662's on the input stages where I need high Z ins and don't have to drive a capacitor, but I'll use LM358's on the outputs. I don't need rail to rail, but I do need single supply operation down to about 6.5V.

Like real jellybeans, I find that I have to keep a couple of flavors of opamp in stock: there is no single best candidate. But they're *all* pretty cheap.

(snip)

Have you ever tried loading the output with a series RC to ground, instead of putting a resistor in series between the output and load? This lowers the output impedance while rolling the high frequency response, instead of raising it. Pick a pair that have a time constant between the period and half the period of the oscillation so the impedance is essentially resistive at the oscillation frequency. Try pairs of about 2 to 1 value steps up and down, keeping the time constant unchanged till you find the optimum response.

In this case I might have tried putting the 620 ohm in series with a 2n7 or a 1n.

Win,

have you used the LM8261 (dual = LM8272) ? It's r-r on input and
output and drives an unlimited capacitive load. It's neat for driving
things like fat fet gates or bypassed Vref rails.

Ok, thanks!

What I inted to build is a digitally controlled direct conversion receiver
or scanner for 1 MHz - 40 MHz AM/SSB/CW, as a RF hobby starter project,
but I'm not sure about the antenna feed-in circuit for this, and there
aren't any radio scanner schematics around, and the ARRL handbook
nor RF coursebooks are very helpful on scanner design...

Seems like a 40MHz low-pass will just have to suffice here?
No bothering about matched antenna impedance an such? (it's for Rx)

> A tuned circuit at the output will obviously be reactive at most

Hmm, yes. I'll go resistive pad then. Maybe. ;)

Sounds interesting! I'll have to read up on that. The detector response
doesn't look good beyond a few MHz, at least not at
http://www.hanssummers.com/radio/polyphase/index.htm but maybe a different
detector capacitor bank arrangement will do better...

many thanks!

Yeah, for IF side (<16kHz) no 40MHz low pass filter is required of
course...

But good to hear the antenna side doesn't require one either. Certainly
gets much simpler. :)

> Of course direct conversion will be
> difficult with AM due to the heterodyne, though you could possible go to
> some sort of synchronous detector. I was looking at the new AD995X series of
> DDS when they become available - they can output to 160 MHz and you divide
> by 4 to get quadrature outputs for the LO.

Actually, you can get samples of their AD9854, "CMOS 300 MHz Quadrature
Complete-DDS Synthesizer" (which I've already ordered samples for on last
weekend). It has simultaneous quadrature I/Q outputs on-board. Just LP
filter these and there you go... :) But it's "only" usable up to
1/3*300MHz = 100MHz LO or thereabouts.
The AD9954 seems to be a "normal" DDS, just 180 deg phase shifted
outputs. At least if the preliminary datasheet is to be trusted.

cheers,

- Jan

I am not to read all of the replies first, but here goes:

Simply use the output transformer and speaker from an
AA5 tube radio. It will be close enough to 2k ohms to work.

None?

Is there something that would keep a transformer from working?
One of those teenly little RatShack audio output transformers
would present an impedance in the right neighborhood to the
diode-and-coil.

The one on my desk is 1K Ohms to 8 Ohms. Seems a bit low, but there
are others available.

I have been reading some of this thread and am wondering if anyone ever
measured the source impedance of the output of a "typical" crystal set.

That shouldn't be hard to do. The biggest problem would be to decide
the configuration of the crystal set / antenna.

Bill K7NOM

978. Re: mixer and tank question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-06 03:19:04 UTC
From: Dan Tayloe <dtayloe@cox.net>
Message-ID: <3E41D49B.690AE9AE@cox.net>
Source record: 37932

A 40 MHz low pass filter will not be good enough. Any detector you use, whether a Tayloe detector or a diode mixer will respond to harmonics, especially odd harmonics. I would suggest that you use sharp low pass filters placed at least on binary frequency values, i.e., 40 MHz, 20 MHz, 10 MHz, 5 MHz, etc.

This will help keep out higher order harmonics out of the receiver. For this type of application, the Tayloe detector is good because it has inherent rejection of signals away from the detection frequency.

I have worked with a pair of the AD9851 (?) DDSs phase locked 90 degrees apart and found that they caused a lot of noise in the Tayloe type detector above 14 MHz or so. If you want to go to 40 MHz, it may be better to use a normal diode bridge since they are not as susceptible to the DDS LO noise as that detector. The Tayloe detector works best at these higher frequencies with a clean LO from a good quality analog VFO.

The Tayloe detector is essentially an R/C low pass filter that has been aliased to the incoming frequency. The R is the system impedance, and the C is the detection caps. The detector capacitors integrate the incoming RF signal pulses producing a smoothed difference frequency, and suppressing off frequency signals by the R/C roll off. The 4:1 duty cycle of the mux produces four phases, 0, 90, 180, and 270 degree outputs. Each output is roughly 4x the impedance of the input (single 50 ohm in, four 200 ohm outputs). The detector has only 0.9 db of loss because of the integrating properties and because only a difference frequency is produced (no sum). Since the normal 4:1 mux chip is a dual part (two muxs), a double balanced version is does not require any additional parts other than an input transformer to feed the two halves. Both halves of the double balanced detector share the same four detector caps.

In any event, beware that a DDS has spurs that will pick up off frequency signals, especially if the front end is a low pass filter and not the tighter ham band only bandpass filter.

979. Solid state AM Modulation-Help?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-06 04:12:20 UTC
From: Michael Franks <pikemike@nnex.net>
Message-ID: <v43o5jirgmtjbf@corp.supernews.com>
Source record: 37933

I am interested in building a solid state AM transmiter (80 and 40 meters).
Would like to have xtal control, about 50 watts. Anyone know of an article
about a project like this ??...What is the transistor equivalent of "Plate
Modulation" ??

Please respond via Email...TNX and 73

980. Convert 110v device to 110/220v???

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-06 05:30:06 UTC
From: Dwight Stewart <stewart@say.net>
Message-ID: <BA675D0D.D6E9%stewart@say.net>
Source record: 37934

We're moving to Europe for several years and I'd like to convert a 110v stereo system subwoofer to 110/220v (switchable or auto sensing).

A quick look inside suggests it would not be too difficult, but what do I know (my knowledge of electronics is basic). However, if it is indeed possible (and I don't see why it isn't), I do know I can do it if someone tells me how.

Anyway, here is what I have. Inside the subwoofer, there is a transformer that powers a small circuit board (the crossover). The numbers on the transformer are E128081 and LF5730-16-3. The faceplate says the input is 32w (120v, 60 Hz).

There are two red wires coming off the main power switch to the transformer. The red wires and power cord wires are sealed, so I can't really see exactly how they are connected. I guess I'll discover that once I start the conversion.

On the other side of the transformer, there are three wires coming off the transformer to the circuit board. The wires are yellow, yellow with black letters, and black.

Finally, there is a ground wire connected to the bolt holding the transformer. This seems to be the ground for both the circuit board and metal faceplate.

Is this conversion possible? What do I need (components and part numbers)? How would I do it (wiring steps)? And finally, is there anything special I should be aware of while doing this.

Okay, I know I'm asking a lot but the newsgroups are my last hope. I've already been turned down by two electronic stores (one wasn't willing to do it and the other tried to sell me a new subwoofer - 110v only of course). Because of that, your help is most appreciated.

And, yes, I know this has nothing to do with ham radio. But I also know the homebrew crowd seldom limit their activities to just ham radio. So, if anyone can provide answers, that person is most likely to be found here.

Source record: 37923

If you are doing a direct conversion you will not need a filter at 40 MHz as the signal is converted direct to audio. Of course direct conversion will be difficult with AM due to the heterodyne, though you could possible go to some sort of synchronous detector. I was looking at the new AD995X series of DDS when they become available - they can output to 160 MHz and you divide by 4 to get quadrature outputs for the LO.

Possible - Yes. Pointless - Yes.

It would be far easier for you to buy a cased autotransformer to run your hi-fi off 110V in Europe. These are available for various power ratings from Electronics suppliers (not the high street). You can get these with the right plugs and sockets already fitted.

To convert your equipment would probably require a replacement transformer which may not fit in the case. With 220V, if you don't know what you are doing, we could also soon have one less member in the group.

Many old crystal sets specified a piezo earpiece because of the high
impedance. They were still common in those plug in the ear earpieces
that came with the miniature 1960/1970's miniature transistor radios.

Anyway the OPs request for a 2000 ohm speaker loads the resonant
circuit quite heavily, so I would suggest looking for those piezo
earpieces.

with only 32w input it would be quite easy to use a small 220v/110v
transformer as an auto transformer. They are readily available over
here, costing about 10-15 dollars. The 220v potentially is'nt too
frightening HI.

If you like Rube Goldberg projects -- (how often do we substitute a complex solution for an easy one?)

For a subwoofer you could easily use an off-line switching supply with a pair of chokes (100uH) and linear regulators to take care of the spikes. The off-line switcher chips from On-Semi will take 90 to 240 volts and there is a PCB layout right on ON-Semi's website.

============
The simplest way to make your 110 V equipment suitable for 230 V in Europe
is to buy a 50 Hz isolation transformer (in Europe) or using an existing
110/230 V - 50Hz transformer in auto-transformer mode using a single tapped
transformer winding. This can be safely done if the transformer is not
marginal ,hence can normally handle say 50 -100 Watts (using your 32 Watts
equipment)

While normally living in Scotland ,I am doing the same when visiting the USA
to
supply low power 230V equipment with 115-120V
using a relatively large 50 Hz transformer in auto-transformer
mode.

However there is another matter namely that of FREQUENCY.

A transformer designed for 50 Hz usually works well on 60Hz , but not always
the other way around.

If the 60 Hz transformer is marginal (capacity wise) it MIGHT get hot when
used on a 50Hz supply.

If that would appear to be the case with your specific equipment , I would
suggest you buy a small replacement 50Hz equivalent transformer when in
Europe .
But before doing that measure the output voltage(s) of the current
transformer while still in the USA.

BTW in EU countries the AC -50 Hz domestic supply voltage has now been
harmonised to 230 Volts ,meaning that in Britain the 240 V has been somewhat
reduced and in continental Europe the voltage has been increased from 220 to
about 230 V ,such that consumer electric/electronic equipment can be

sold/used across the EU. The equipment voltage rating of equipment with the CE symbol is now usually 220 - 240 V with (sometimes) separate power ratings stated for the extreme supply voltages
Earlier ,for example, a continental clothing iron rated 220V-1500Watts often did not survive for very long when used in Britain.
At my (rural) QTH the supply voltage is nowadays usually 236 - 237 volts .

The crystal+phones circuit can be impedance-matched to the antenna+tuned
circuit by tapping the crystal down the coil.

At the same time the selectivity of the tuned circuit is not damped any more
than necessary.

For 2000-ohm phones first try tapping 2/3rds or 3/4 of the way down the
coil. There will be a marked increase in selectivity.

Why would you want to do that Hank? There are a bunch of the different versions of the hp solid state oscillator around, 204 209 etc., I've seen them for $25 or so at the swaps... The tube versions are preferred by those audio fanatics who are into the "tube sound" anyway.

There's another potential consequence of the lower frequency. If power supply filtering is marginal (which is likely with a consumer item), the voltage will sag too much between cycles, resulting in a potentially very loud 100 Hz hum or buzz. If it's present, the subwoofer should reproduce it very well! The cure for this is to increase the value of the power supply filter capacitor by at least 20% -- or you could just add another capacitor in parallel with the existing one. The added capacitor should have a value at least 1/5 the value of the existing one.

Unfortunately tapping down the tuned circuit will also reduce the
voltage applied to the crystal, but the diode threshold voltage
remains the same, thus reducing the sensitivity. I think it would be a
better idea to let the diode operate at the full RF voltage and only
transform the audio voltage for the low impedance headphones.

It's obvious you have never made or used a crystal set. Why not make one and educate yourself in both elementary practice and theory.

Tap the crystal down the tuning coil until the loudest signal can be heard in the phones. That setting corresponds to the best impedance match (maximum power transfer). It is quite obvious that setting will also give you maximum audio voltage across the phones and maximum audio current through the phones.

If the signal is sufficiently loud then tap the crystal further down the coil to obtain greater selectivity, less damping of the tuned circuit, and less interference from nearby unwanted stations.

Then perhaps you will stop cramming the wrong ideas into genuine novices.

Depends a lot on what frequencies and how accurately you want to measure them

1) At power frequencies,as Wim Ton says, feed your unknown into one input and the time-controlled power frequency into another. Count the "Beats", check the pattern and do the sums to calculate your frequency.Works well to check frequencies that are multples or sub-multiples of the line frequency

2) Near 15kHz: feed your line time-base into one input and puzzle out the frequency by comparing one trace with the other.

3)At BC frequencies: feed your local BC signal and your unknown, as 2). Gets problematic at higher frequencies.

I have run out of ideas, so

4)Buy (or build) a frequency meter. Check against WWV.

G.H.Ireland.

Hey guys/gals,
I downloaded the toolkit for modifying motorola HT's I can't open it because it gives me an error of

```
????????????????????????????????????????????????????????????
? WARNING! WARNING! WARNING! WARNING! WARNING! WARNING! ?
? The MATH DEVICE is either not connected to one of your ?
? LPT ports or the program may not be compatible with this ?
? computer. ?
? (Press ENTER to restart and try again). ?
????????????????????????????????????????????????????????????
```

very strange, anyone have any ideas on how to get it to work? I need to convert some ht600 from 2 to 6 chan. so that they can be useful for a new amateur radio club.

Chris

This Tek 494AP spectrum analyzer comes with all manuals and accessories for coverage between 10 kHz and 26.5 GHz. Built-in frequency counter with 1 Hz resolution and marker capability; too many other features to list. Sweep filters, measure phase noise, check IMD, diagnose parasitics, and impress visitors!

Comes with circuit-board extenders and a full set of manuals. .PDF of operator's manual available on request (whether bidding or not) -- remove spam-blocked portion of my address to email me.

Sounds like the program you have requires a HArdware Key conected to you
Printer Port..

Good Luck..

I'd say the same thing, also some Motorola software is real fussy about
the computers it runs on. About 5 years ago the Coast Guard had to find
some old Heath laptops to program some of their radios.

The 2to6.exe file, as I recall, needs to be run under DOS 6.22. No higher. And, for that matter, you may need to find an old-and-slow machine to run it on.

FWIW: If you just need a few radios programmed <SHAMELESS PLUG ALERT!>, I can deal with it. See http://www.bluefeathertech.com/rf.html

For further assistance with Motorola goodies, see:

http://www.batlabs.com

Good luck.

1003. For all of those hobbiest who love 'keep it simple simon' projects, I've got an amazing FM receiver!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-07 05:10:52 UTC
From: braincambre500@yahoo.com
Message-ID: <85a87c6c.0302062110.70ed67ca@posting.google.com>
Source record: 37956

Hello all,

I try to go to as many electronic/hobbiest forums to post my one transistor FM receiver. I know there are hobbiest out there who love to make simple circuits...and my project definately falls into that category.

I could type for hours telling you of the extra-ordinary sensitivity and selectivity is has...but if you do read what Pedro...Phillip...and Murphy had to say about their maiden journey...you will never know what you are missing. And believe me, that is still an 'understatment'.

Pedro was very sceptical in the beginning of getting a so called 'one' transistor FM receiver to function at all...much less work! But to his amazement, he carried out my instructions to a 't'...and it worked fine!

I call this design...The Radio Shack Special...since all of the parts may be purchased there. I did not want to have hobbiests have to mail order ANYTHING. I kept that is mind with the design.

Yes, it's a one transistor (MPF102) FM receiver. Of course, since the audio out is but a few milli-volts, it had to be beefed up with an LM386.

When you get to my website, just scroll down until you see the words...

The Radio Shack Special Project

...from there you will be on your own...unless, for some reason, you should need my help. I will do anything I can to help you get it to work. I know it works....I have already made 10 of them.

Even if you have never made a simple project before...I even have construction plans on ....how to make your first PCB (printed circuit board)...plus another section on how to make homemade coils...in which these two items are needed for the Radio Shack Special Project.

Do let me know what you intentions are...if you choose to make the project, I would love for you to send pictures and a documentary after you have completed a successful journey. I will then make a special webpage, just for you and your project...for others to have more of an incentive...should they decide to make the project also.

With that said....I will be here at my e-mail address, should you need ANY type of help with the project. That is what I am here for. Not just to post a typical schematic on the WWW, but to let all know that I am your

backboard...should concerns come up along the way.

How does it work? A few HAM operators have asked me that question. I also have the 'theoredical' on the website also....it gives an explanation on how superrenerative receivers operate.

So my friend, do drop me a line should your interest continue. I will make a special folder just for you...for your pictures and documentary of the precious little jewel.

...and let the project begin!

I want to thank each and everyone at this forum for giving me the time to type my request.

Respectfully,

Patrick Cambre Web site address: http://braincambre500.freeservers.com

E-mail address: braincambre500@yahoo.com

P.S. Sometimes my web site goes disabled...by keeping my e-mail on hand, I will personally attend to your concerns.

Yep, after spending eleven years in Europe (ten in Germany and one in Italy), I'm aware of simple 110/220 volt transformers. Sadly, I'm also aware of the nuisance of using them. This will be an extended trip. Because of that, I've replaced just about everything I'm taking with 110/220v items. Sadly, I haven't found a compact subwoofer to satisfy me. If I'm not willing to use a transformer, this leaves two options - convert what I have or hope to find a replacement there. Since I don't like the unknown (finding something there), I'm researching the conversion idea.

This is another major concern. I've seen this with 110v 60Hz items used overseas, particularly with radio and stereo equipment. In fact, I had a shortwave receiver with this problem, as well as a Kenwood stereo receiver. I solved the problems by running the shortwave receiver off batteries and I sold the stereo component to a GI returning to the states.

A guy who converted stuff to 220v at the military PX told me something about this but it didn't make much sense at the time (perhaps because his English was not so perfect). Your explanation is a little more clear.

Thanks to all that responded so far. What I have now sounds simple enough. I need to replace the power transformer with a similar wattage output 220v one. The wiring should be very similar to what exists unless I choose a 110/220v power transformer. If that is the case, I need to add a switch to select the windings based on the voltage used.

Filtering potential hum may be a problem, but Roy suggested some steps I could take to prevent this (increasing the value of the filter capacitor or adding another capacitor in parallel).

Can anyone think of anything else or add anything to what I already have?

Have you considered buying a new sub? They cost about £100. Or, you could buy some decent speakers so you don't need a sub at all for say £500. You really can get good stuff here - we of course maintain it is better than what you can get over there. What does it cost to ship all this stuff from W5?

I am aware of the 50/60 Hz issue but many US devices are able to cope. The 100Hz ripple should only happen at high load. The 32W input rating seems very low for a compact sub. It translates to perhaps 25W RMS. LF needs power as small sized drivers are inefficient, unless resonant - and we don't want that do we!

1009. Looking for website, TV tuner modification

1014. Automatic band change for Yaesu Quadra and FL-7000 amplifiers

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-07 16:32:40 UTC
From: Jerry Flanders <SeeSignature@below.com>
Message-ID: <apn74v8891j88k61mghth49vijbke5frah@4ax.com>
Source record: 37967

My Quadra amplifier now comes on whenever I turn on my ICOM IC-756PRO, follows it from band to band from 160 meters to 6 meters (all WARC bands included), and selects the appropriate antenna port and ATU presets just as if it was connected to a Yaesu transceiver.

This can also be done with most other modern transceivers.

See http://www.qsl.net/ab4oj/quadra/w4uk.html for full details and cable wiring instructions.

No mods to the transceiver or the amp are required.

FL-7000 users can apply the same information, but actual wiring instructions are only provided for the Quadra. (FL-7000 uses a different plug).

More:

Yaesu's method of band changing uses a TTL level 4-bit code. When the code is generated inside compatible Yaesu transceivers and fed to the amp by the Yaesu "band data" cable, the amplifier follows the transceiver from band to band and also enables antenna tuner presets . Any method of generating a similar code will cause the amp to switch just as if the transceiver were a Yaesu.

Ham logging program developers followed the Yaesu code to implement what they typically call "antenna relay" switching on a LPT port. Most current logging programs provide antenna relay signals, so those logging programs emulate the band-data signals of a genuine Yaesu-compatible transceiver. The LPT port provides TTL level signals, the Yaesu amp uses them directly - only a cable is required to connect the LPT to the amp. I used my Yaesu band-data cable by adding a $3 plug from radio Shack.

1015. Need coil form

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-07 16:40:32 UTC
From: jcplpsm@aol.communicate
Message-ID: <20030207114032.08918.00000244@mb-cg.aol.com>
Source record: 37968

Does anyone have a good source for coil forms? T have tried all my usual sources, AES, Dicks, etc. I need a form that is 2 3/4" long with an inside diameter of 3/8". The outside diameter can't be more than 9/16", as this is the needed dimension, but can be smaller. I can always build it up. The original form is phenolic, but I believe paper will do fine. The inside diameter is critical as it is slug tuned.

Thanks for any suggestions in advance.

1017. LM7812 Diode Adjustment

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-07 19:11:13 UTC
From: Larry W <larry@scuttlebutt.org>
Message-ID: <Xns931B8F0A05170scuttlebutt@65.24.2.12>
Source record: 37970

Many years ago there was an article in CQ magazine on building a simple power supply using the LM7812. The output voltage of the LM7812 could be tweaked to whatever voltage in .6 volt increments by using diodes in the ground circuit of the LM7812. By using three diodes the output voltage could be adjusted to exactly 13.8 volts. Since moving I have lost the article in the shuffle and would really appreciate if someone could give some help on finding this schematic.

Thank,

Larry

The DC and AC loads are critical. Even with 2K earphones, an improvement
in distortion can be had by using a series resistor bypassed with an audio
capacitor. Ben Tongue (of Blonder Tongue fame) has a great website that

delves into crystal detector loading.

The schematic is easy - just put the string of diodes between ground and the common lead of the LM7812, with the cathode ends towards ground. Three silicon diodes will give about 0.6 x 3 or a 1.8 volt increase in the output.

Three diodes will cause the output vary with temperature at the rate of
about minus 6 - 7 mV per degree C, if that matters.

Hello,
You can go to website for Fairchild semi or On semi and find the spec.
But TO220 package, you will see the left pin is input and middle pin
is ground and right pin is for output. Insert any silicon diode like
1N4001 series between Pin 2 and ground and keep the cathode side (
where the band is marked)
to the ground side, this will raise 0.6V or so.
But if you use more than 1A, you had better try LDO. (Low voltage
drop regulators) LM7812 need at least 4V head room voltage so if you
draw 1A, you are talking about 4W dissipation in that IC. But if your
can maintain input voltage to 14.8V or so then voltage drop using LDO
will be less than 1V so the total dissipation on that rgulator is 1W,
much cooler and need small heat sink.
There are 3A versions available in that same package. Go to On semi
website or National semi and look for LDO. You can find adjustable
type as well.
Good luck. YOU can get some samples from them at free of charge.

Thank you for reading my msg!

I am building a HB windom antenna according to:
http://www.packetradio.com/windom.htm

According to the diagram I need to connect the short leg to NEG ang
long leg to POS. I just recd the HI-Q 4:1 and there is no
documentation on which side is what. Ohming is not on option, due to
being DC grounded.
The instructions in the HI-Q say, "Do NOT disassemble the HI-Q Balun.
Once any of the hooks are disassembled, the balun can not be
reassembled."
Plus the PVC is glued well.

Thank you for the help!

I remember seeing an article stating that raisng the ground reference
using diodes could lead to disasterous results if a short should
occure i.e short circuit of internal pass transistor and leading to
full unregulated voltage at output. Not sure if it was a specific
brand of 7812.

Why not use an adjustable chip like LM317?

If you want to use diodes, make sure there is enough bias currect, to
get the wanted voltage. And make an acid test, short the output before
using the p.s.

Cheers
Lasse SM5GLC

A crystal earpiece would be OK, but you may need to put a 100k resistor
across it. Or if you're really desperate, a piezo transducer will also work
(though the recovered audio will be poor).

Unless you're really close to the transmitter or have a very efficient
antenna you will not drive a speaker with a simple crystal set unless it's
followed by an amplifer stage.

I would go further and build a 2 transistor regenerative set. If adding a
transistor
amplifier doubles the performance of the crystal set, making it regenerative
will
increase it 100 fold. You will be able to drive a speaker on local stations
and
get interstate stations at night.

This is a disaster, but I have never caused it in my experience by raising the ground reference.
I have used a 7805 and a 6 volt zener + diode and got close to a 7812. Worked fine for me. The reason I used this odd combination is because that is what I had.

>If you want to use diodes, make sure there is enough bias currect, to

The regulation may not be as stiff, but it will work, and no don't short the output. I have never done that. If you are sending this up in the Space Shuttle, maybe do that before launch, but for Amateur use don't bother.

My experience with the "full unregulated. voltage on output" was when the input voltage
fell to zero (short on input) and the large output capacitor put a reverse voltage

on the internal pass transistor. That resulted in the unregulated. input being passed through
to the output.

Other wise I have used the diode trick a couple of times with good results.

You might also look for a product called the Betsi. This was a motherboard, originally intended for the Commodore Pet, which provided for S-100 expansion. The name was changed from Petsi to Betsi due to legal pressure from Commodore. IIRC, the KIM has the same parallel port as the Pet.

I would add to this the caution that Tektronix discontinued their
entire analog 'scope line in January of 2000, and that they seem bound
and determined to wipe out all traces of support for anything over a
couple of years old.

They have, unfortunately, mutated from a company that was built by
and for engineers and techs into Just Another Money-Grubbing Dot-Bomb.
Whether this degrading contamination has affected all of their repair
stations remains to be seen, but don't be in the least surprised if they
try to convince you to buy one of their new offshore-crap 'scopes instead
of fixing your 465B.

Good luck.

Any self-respecting vintage radio purist would blanche at such a
suggestion. One assumes the OP was keen to stick to the traditional
set-up. If you're going to start adding externally-powered refinements
you kiss goodbye to that spirit. He might as well go off and build
himself a PLL-controlled triple-conversion superhet!

The op notes on most of these devices recommend using a diode from input to output in order to guard against shorting the internal pass transistor when the input drops to zero and the output has large capacitors across it. Few designers appear to use this diode.

You might be surprized how small a signal the human ear can preceive from a speaker. I once did some tests with a carefully measured sine wave into an ordinary speaker. One milliwatt was clearly audible and only when down into the microwatts did the tone disappear. Try it, you might be amazed.

Regens are rather vintage, too. After using one for a while, one is grateful Armstrong went on to the next step. It is interesting to work your way through radio history. Phylogeny recaptitulates ontogeny or something.

So I understand from this that the switches are for charge rate, and only
one of them should normally be depressed at a time. And that they are
high, medium, and low rate from left to right.

BP-4 has no glued plate, but it has equivalent molded directly in and it
operates the center switch. Rapid charge BP-5 uses the left switch and
slow charge BP-3 the one on the right.

I should ask Icom for the service info.

>The rapid charge BP series ie: BP-5, BP-7, BP-8 all are controlled by

I never did know why the BP-5 would stop automatically and the BP-3 would
not, but yes, the temp rise idea would not work so well for slow charging.

I have the EB104 kit. Looks like a nice little amp but keep in mind
several things:

- I think the intermod performance is a tad low but still usable.
- this is just the amp board but since it is 600 W out you need to
develop
- TR switching
- SWR protection - transistors are 250 US per 4.
- you need good thermal protection. Recommend the copper plate heat
spreader
but you will need to smooth out the surface. Mine had scratch, bumps
and would
not sit flat on a heat sink until I sanded down the edges.
- you will need a wopper of a heat sink and probably some fan cooling
- you also need to get a 20 Amp 40 - 50 V power supply for this.

- drive level is around 5 Watts. If you are driving it with a 100W rig
you need to
1) turn the power down
2) put in some input power protection incase you forget 1)
3) develop some high power attenuators. Ohmite makes some inexpensive
35 W
power resistors in a T220 package which should do the trick.

- you will of course need high power harmonic filters. CCI has some of
these.

You should check the Philip's power amplifier ap notes for performance
comparison
e.g. IP3. also check the Ameriton amplifiers. They have a 4 MRF150 amp
as well.
Maybe you could just get their power supply if you want to build the
EB104.

Good luck. Let me know how things go.

A "standard test tone" in telephony a half century ago was
the "Volume Unit" given in decibels based on 1.0 mW into
a 600 Ohm characteristic impedance line. With a military
version of Trimm 2000 Ohm headphones peaking in
response at about 1 KHz, that single little milliWatt was
quite uncomfortable to hear for more than a few seconds.

With all 24 channels of a microwave radio relay terminal
set for nominal maximum of 0 VU, we could just barely
sense random channel noise at 40 db down from 0 VU...if
the rest of the terminal room was quiet (nine terminals all
told, only two very small squirrel cage blowers in each
terminal). Barely perceptible noise to young ears. :-)

What has been slightly overlooked is the efficiency of
close-coupling any headphones to the ear...much higher
than speakers...unless the speakers are used AS
headphones (somewhat of a danger there with ordinary
tube/transistor radios).

E = Square-root (P * R). If 2000 Ohm headphones get
a microwatt of audio, the voltage across the phones is
44.7 mV. If the diode detector is 50% efficient and AM
input signals are at peak modulation, the antenna
voltage would be the same 44.7 mV, a fairly strong

signal. [just an approximation, not absolute]

The most recent Mouser catalog shows crystal ear-
phones with impedances of several MegOhms (!).
[www.mouser.com] Cheap at $1.85 to $2.03 each
made by Kobitone. Adding diodes to form a voltage
doubler, tripler, etc., would possibly increase the
earphone level. Those very high-Z earphones take
low current and would fit the voltage multiplier low-
current requirements. Just a thought...

>I have the EB104 kit. Looks like a nice little amp but keep in mind
>several things:

I ditto everything Bill said. I got 2 of the EB104 boards and homebrewed power splitters and combiners for a 1200 watt amp. I think this is equivalent to the Yeasu solid state amp that uses the 8 MRF150s. I currently have band switched LPF for 160, 80 and 40m. The amp works fine, and as near as I can tell I get 1200 watts pep into a 50 ohm load.
I built the 50v 40 amp linear supply from the junkbox. It is rather massive. In the future I am either building a SMPS or try to find one surplus. I noticed Fair Radio has one for around $100, but the shipping weight is 100lbs. The EB104 is a good starting point, but to have an amplifier that you can safely use with a 100 watt transceiver requires a LOT more circuitry and expense.

Remeber that with low current comes the requirement for high voltage
(relatively speaking). Like they taught us in Electronics 101, maximum
power transfer occurs when source impedance = load impedance.

So what is the source impedance of a crystal set? Anyone know?

The 465B was one of Tek's best scopes ever. Have you considered
getting a service manual and fixing it yourself? If you use and
understand a scope, you can probably also fix it, with the help of the
manual.

There's also plenty of good help available on the newsgroups.
Sci.electronics.repair would be the best place to ask.

I worked for three years on the 465 and 465B production line at Tektronix
calibrating and repairing. I would recommend do-it-yourself for VERY
experienced techs only. Especially don't mess with the adjustments for
gain compensation. You'll never get it back right without some rather
expensive test equipment.

Source record: 37864

Hi All

I bought a cheap surplus 4x20 LCD display last summer. While it worked reliably, it had miserable contrast and poor viewing angle. I thought that was the reason it was surplus and cheap and did not follow up hi hi.

I just found that my VSS wire connection to the display was broken (bad Jim) and when I connected it, the display started to perform very well.

The return apparently was taking a circuitous path through the contrast line (which I had connected properly).

So, if you have a display that "almost" works, check the VSS connection.

==========
You might wish to consider the MAHA -C777 Plus automatic universal charger /conditioner which charges any Nicad or NiMH cell or pack up to 14.4V ,even Lithium -ion cells.
The unit analyses/conditions/charges any shape of battery ,also those used for model racing cars ,mobile phones ,video cameras etc. I use both the above model as well as the older version (without display unit) and am very pleased with both .
Note : I have no other connection with MAHA Energy Inc other than being a satisfied customer.

Is this the scope that's first class until some gold-plating wears off
somewhere and you just have to junk it? Sounds a terrible waste, but I
gather there's nothing one can do about it.

Understood and empathized. I tried getting away from the "packaged" audio amplifiers for speaker and phones in my products because at some time in the future even the venerable LM386 is going to be history. (Did I hear somebody say "The 6V6 will never die."?)

Put an LM324 inside a feedback loop of the usual comp-symm 3-transistor output stage and simulated it, just not far enough in frequency. The hardware breadboard sang like a bird at about 800 kHz. and I had only simulated it to 500 kHz. Bit in the butt again.

I'm not familiar with that radio, but if it's like most, the plugs are
mono. One for the speaker, and one for the mike. The switching is done
on the same "hot" mike line, and is isolated by a resister usually.
There is no separate "switching " line as there is in many larger
radios. MK

G'day

What you need Doug is an old speaker transformer from a tube radio. These are typically designed to convert the 5000 ohms or so plate circuit impedance to match a 3 or 8 ohm speaker. If you wire the High resistance winding of the transformer where the Hi impedance phones went and wire the speaker across the low resistance winding you can get surprisingly good results. I still have a crystal set the when used with a very high efficiency 5" speaker gave quite audible results in a quiet workshop when used with a 30 Ft antenna and from a local station running 50 Kw about 10 miles away. It is very important that the sets coils are accurately matched to the load of the antenna and the detector circuit. This is where the use of multi tapped coils where everything can be adjusted for best results.
Look up some of the more complex Xtal sets that have adjustable coils on the net and you'll see just what I mean.
Of course unless the station is next door you won't get really worthwhile volume.
Regards Cliff Wright ZL1BDA ex G3NIA.

There is (was?) an outfit named NKX, that provided REBUILT channel elements for about, as i remember, 35 bucks a piece. a good place to look for old elements is on ebay. but, with the MSR-2000, this radio in new enuff that may not be many surplus to be had. another good place (and still in business) is International crystal- tho dont know their prices, but should be able to find their web site. also, kxn 1086/ 88 sounds like maybe used by other motorola radios, but been too long ago since was full-blown radioman--- jim nn7k

Source record: 37876

Hi Dwight,

Besides the 60Hz vs 50 Hz filtering that Roy mentioned, another thing to consider is that since your transformer specifically says 60 Hz, it has a bit less inductance (in other words, turns of wire) and a bit lower saturation (roughly, mass of iron) than one designed for 50 Hz. The 50 Hz transformers generally say "50/60 Hz".

Even if you transform the 220 to 110V, the subwoofer's transformer would probably run hot. It will *definitely* be hotter than at 60 Hz, just how hot you'll have to see.

Another idea: instead of building a switcher, buy a big 12V power supply, like a 13.8V 25A (if you need say 300W) that runs off 220V. This might run you at least $100. Too bad the $60 RadioShack sale one is only 110V. A switching supply would be more efficient, smaller, lighter, cooler. Then use an off-the-shelf 12V to 110V converter. These run around $60 for a 300W one these days and can be found at any *mart store. You may need some LC filtering since the pseudo-sine wave output has sharp edges and may cause hum, but may not be required depending on how well your sub is designed. The fan might annoy you but is needed at high power.

Yet another idea would be to buy the same transformer and put the two in series. Make sure the phase is correct.

Boy, this subwoofer must be so special that you can't just buy another one... :-)

Regards,

-Vince

Im trying to build a radar system that will detect another device (also to be built by me) within a 1/4 mile radius. I really need some of the smart people's advice and direction as to how to accomplish this.

the device will not be in the air or under water, it will be like a person on land. The radar detector should be able to locate that "person" (to some degree) (I am a software engineer and can interpret the signals if presented properly)...

Thank you so much for your help!

ps. the email is fake, but I will check online messages.

> gather there's nothing one can do about it.
>

You gather wrong. They used some very tiny little contacts that look like tuning forks about the size of a match head to do the switching in the attenuators and other circuits. The contact pressure is feather light, so gold does not wear off them, they just lose tension or some crud accumulates and they don't make good contact. If you are very, very careful, you can bend them very slightly downward and they will magically work again. It is *real* easy to bend them too far and then you have a problem. Even then it isn't hopeless, just much more difficult.

Tektronix patented the design and it was pretty clever since it eliminated nearly all lead inductance in the switches, but it was indeed finicky. I've been out of the business for a while, but I'm sure modern scopes use solid state switches which should be far more reliable.

The 465 and 465B were at the time the best selling scope in the world and customer loyalty was fantastic. Our customers used to say "I'll buy any brand of scope as long as it's blue and comes from Beaverton, Oregon".

Trivia buffs: How many 465A's were made?
Answer: None. Model numbers went directly from the 465 to the 465B. Even we who worked there never knew why. That's the only Tek scope I know of that skipped a letter like that.

1082. Re: Tektronix 465B

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-11 02:42:38 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <v4gop2rlm5n01f@corp.supernews.com>
Source record: 37884

I'm the one who brought up the issue of gold plating wearing off 465 switch contacts. On one of Tek's "road shows" -- a scope seminar -- I met some fellows who said that had been the fate of their very heavily used 465, and they were at the seminar to learn what was more currently available. They said that the Tek service center had told them their scope was a goner because the plating was worn off the contacts, which were circuit board traces, and they couldn't be replaced. I recalled that some of the lever switches (for things like AC/DC coupling) on some of Tek's scopes were made by staking a plastic cover over a switch assembly which used heavily gold plated circuit board traces as contacts, and thought that was how some of the 465's switches were made. I have a 455, and the trigger source and coupling switches are constructed that way. On scopes using that type of switch, wearing through the gold plating would constitute an unrepairable problem. Overall, though, the switches were very reliable, and I personally heard only of the one case of wearout.

But Bill has had a good deal of actual experience with 465s and I haven't, so I'll certainly defer to his much greater knowledge of the instrument. If I'm mistaken about the 465 switch construction, I apologize for misleading people. I do know that the 465 established an enviable reputation for reliability, and any wearout mechanism would undoubtedly require a great deal of heavy use. I didn't mean to imply that this is a common problem with the 465 or any other scope -- just that it would be something for a prudent buyer to look for before buying a heavily used instrument, since it would constitute an unrepairable problem.

Roy Lewallen, W7EL

I suppose you could do it, but it would be a whole lot of work and
without a LOT of trial and error it probably wouldn't work as well as
the original 200CD design. The 200CD Wein Bridge oscillator is really
quite excellent over its range of operation. There was a reason why HP
marketed these successfully for nearly 30 years.

I don't doubt that was said, but I do doubt if it's really true. Even if the gold plating wore off, there is the base metal under it and contact could still be made if the contact were bent down some more and the surfaces were clean. I suspect the service guys either didn't know the trick or just didn't want to bother. And it is a trick - someone had to show me how to do it. Their approach was most likely to just change the whole assembly, and when those became unavailable due to age, that was that. We are talking about a pretty old scope here. I wish I could have gotten their castoffs. :-)

If you think about it, gold is nice but not really necessary for contact to be made. Just cleanliness and a minute amount of pressure. Restoring those will fix it every time.

As another poster has said, ultrasonic sound waves, or infrared light is your best option. Radar, as in radio waves is just about useless at this close in range, and to get good resolution with a reasonable antenna is just to complicated. I have done a similar project with ultrasonics to detect horses out on pasture, and intruders around a lake. Still have pieces of it around.

I owned one of the SDK-85 units, and I have built several duplicates
from scratch. One is a dedicated Eprom programmer still in use today.
I am guessing I could photocopy some stuff for you. B.T.W., I have re-
written the 'Monitor' program about 50 differant times, and am probably
the expert on it by now. Post a reply to the group if you are interested.
My addy is totally bogus for anti-spam-ability, but I can get with you
directly if your addy is a good one.

If you are really trying to "detect another device" then why aren't
you considering an active transponder rather than a passive
reflection-type system?

I suppose one could just frequently spray the worn contacts with
switch cleaner/lube, but I suspect it wouldn't be long before the
switches became noisy again. :-(

Yes, I'd be interested. Does the documentation list the source code for
the monitor program as well? How many pages of documentation are there
(would it be feasible [ie economical] to copy all pages)?

Has anyone tried one of those el-cheapo gold plating kits that get
advertised on TV in the wee hours? If all that's needed is a thin gold
coating, it sounds like that'd be a way to get it. Have to start off
with a clean surface, of course, but that's not at all hard.

Production was already running when I started at Tek in 1977 and still going strong when I transferred to another department in 1980. I remember the announcement about production ending but I don't recall the exact year. Early '80s sometime.

I think the reason they're so sought after is they work extremely well and are very easy to use. The trigger circuit was especially good, well ahead of it's time. Easy to configure as to trigger source and mode and it always seemed to do just what you wanted. I've used lots of other scopes that seemed to have a mind of their own when it comes to triggering. If you've ever used one you'll know what I'm talking about. And nowdays, the price is pretty good too. I got a 465B off eBay a couple of years ago for $250. Works fine, even the switches. Incidentally, the new price back then was in the $2500 range, a lot of money for a portable scope but we sold a ton of 'em. Quality talks.

That's true. I didn't mean to imply that contacts with the gold worn off were just as good. The gold is there for a good reason, it's just not absolutely necessary. Given regular cleaning, the scope will work without it.

A synthesised rig will work if you can program just the frequencies he needs in to memory. If the rig uses UP and DOWN buttons on the mic, then he only needs to count the button pushes from the first to last memory. This works as long as the memories don't roll over. If they do, most rigs beep at memory position 1. Probably easier to find one of these than a crystal controlled rig, and more versatile if you need to add or change frequencies later.

Hi Bill,

In this case there are not any noticeable clicks form the K2. The
picture noted below may appear a little sharper than reality due to
the way he sampled the signal with his digital scope. There actually
is a little more rounding on the trailing edge than he shows.

Both Wayne and I are CW ops and are pretty picky about the sound of
our rigs. We paid a lot of attention to the CW wave shape design and
we tested it extensively to insure it didn't create key clicks.

Bandwidth was 100 MHz at -3 dB. The input impedance as best as I recall
was 1 meg shunted with aprox 20pf. Pretty sure on the 1 meg, a little less
sure on the 20pf.

It's been 23 years. :-)

Truth is that I dont know much about what the best options are... I
am serious about building something that will work like this, but I
guess I need some guidance as to what avenue would take me to the best
solution. If anyone would like to give me some insight as to what
they have on their mind I would love to hear it..

Again thanks everyone for responding, Any guidance would be great.

I listed it on ebay for a buck -- the 8068 regulator tubes were damaged and these are impossible to source. I believe they are a very high voltage tetrode with octal base. If someone is looking for a microwave power supply (I suppose Kepco was kept in business by Grumman out on LI, or whatever.) I just want the thing out of the basement.

Check West Marine catalog [www.westmarine.com] for ideas on short range radar, freq, pwr, etc. No experience with radars of less than 100 mile range. Even fire control radar for 3" gun mount on DER had 10-mile range. Not my equipment. Troops and helo crewmembers in 'nam scattered lumps looking like animal fecal matter which would transmit vibrations of equipment, troops in boots or VC wearing sandals and carrying supplies on Ho Chi Minh Trail to receivers for evaluation. Saw some advertised in Fair Radio catalog some years back. Check with www.fairradio.com.

I recently programmed a 706 for a blind friend. What he did was to have me program an FM broadcast station on a particular channel, then he could count from that channel (most synthesized rigs have encoders with no end stops so if you ever loose your place you're done).

I had more or less assumed that the 706 was impossible for a blind ham because of the menu, but some of the menu beeps turn out to have a slightly different sound than others, so he was able to navigate the menus quite well.

On a 440 only rig I don't know of any places you could find an "always on" station like that, but on a dual bander you could program the weather station into channel 1, then his stations into 2, 3, and 4. He would then be able to tune around until he heard the computer voice and count from there.

..

I have a manual. What you stated is exactly what the book says.
Gives a tolerance of 2% on the 1 M impedance.

My 465 scope currently has lost its HV supply. I assume I will be
able to fix it, but haven't gotten around to a seroius look yet. Is
there a common failure in the HV supply that I should look for
first?

Something that would help in figuring what will be useful is a better understanding of how you intend to use the system.

For example, if you are planning to place a bug on a car and be able to follow it, that is one type of application, or if you want to place a bug on a hot air ballon to let you find it when it lands, that's a very different sort of thing.

So, we could take guesses and make suggestions, but they may not be anywhere near the right solution.....

==========

How precise does the location have to be ?

Is this in open country, or in city areas with cars and so on ?

How large can the device to be detected be physically ?

How long does the battery have to last in the device to be detected ?

==========

In other words, exactly what do you want to be able to use the device for ?

Given the answers to these questions, we might be able to give better suggestions.

Jim

HV failures are pretty rare so I can't really help much there. Check all the lower voltage power supplies first. There are half a dozen or more. The 55 volt supply is the "master" supply in the sense that all others are referenced to it. Be sure it is correct first before checking the others. An error there will foul up everything in the scope.

It might be easier to find a Kenwood with the voice synthesizer which will allow him to do much more then just the three channels. I don't know about recent rigs, but I remember it being an available option on the TW-4000A, which includes two meters also.

Another possibility is one of the thumbwheel programmed rigs. A Braille mark on each thumbwheel would provide a reference.

You see, I don't recall very many crystal UHF ham radios except for GE/Motorola/RCA, and those are a little ancient and cumbersome. Also very cheap these days, I have to admit.

Oooh, touched a nerve on 'ol Fred there.

To answer the question, it's "collector modulation" if you're using a
common emitter circuit, which most designs do.

Fred forgot to mention the more pleasing audio of good AM. Listen around
29.0 when the band is open, then go back to SSB and compare.

Actually there's no comparison, so never mind.

In fact, my friend's 706 has a voice synthesizer, which is useful to him on HF where there really isn't much of an alternative. But on VHF/UHF, you would rather just go 2 clicks and be there. He has, if I recall, around 2 dozen channels programmed, but he also operates HF. Clicking past the broadcast channel is a little more convenient than pressing the "talk the frequency" button and waiting to hear the droning voice.

They are both nice radios. The SST has more limited tuning range since it is VXO. I understand these rigs are used a lot in some of the QRP contests because they can be extremely lightweight and the tuning range limitation is not an issue.

I know at least on 20m, the SST is extremely sensitive. This is good in that it will pick up very tiny signals given good band conditions (such as other SSTs!), but would not be good handling large neighboring signals of a QRO cw contest.

I think the SW+ series has a VFO with a broader range of tuning. If you want to work QRP contests as well as drop down to the bottom of the band and try QRP Dxing, then this is a better rig.

ok the general idea is to attach a small device to my cat. It tends
to get lost easily (or likes to hide), so on those cold winter nights
we want to know where we can go out and find it.

location = suburbs.
distance = less than a mile radius is needed
battery life = 8+ hours
size = small as possible

what about the transponder idea? could that be a valid solution?

Well, a device to attach to a cat poses some interesting problems. It has GOT to be very small and lightweight or else the cat will have problems. This means a very small battery, and no real antenna to speak of.

So, considering cars, houses, and whatever between you and the cat, it will be nearly impossible to get any reasonable range out of it. Plus, the small battery means extremely limited operating time and a very low power transmit signal.

To Triangulate on the signal, you'd need two base recievers and probably a portable unit too. Tracking RF to the degree of being able to find a cat is a time consuming business.

Some sort of transponder, which uses very little power until it gets a command signal might help the battery life, but even so the range would be a big problem.

A radio transponder would need a reciever and a transmitter and a control ciruit. This all add's up to a physically bulky package and that isn't even thinking about the battery or any sort of antenna.

You'd need to use a very high frequency to make a small antenna work with any degree of efficiency, and that all takes parts, space, and battery power.

Not to mention probably being illegal, with an unliscensed radio transmitter....

==========

Possibly some sort of acoustic system, which uses a microphone and an ultrasonic beeper could work to some degree.

Still, no range, really. But if you walked, or possibly drove, around the neighborhood pulsing the command tone, the unit could 'hear' it and activate the ultrasonic beeper in response. You'd have to use directional microphones to track it down but it might work after a fashion.

==========

All in all, this is NOT a simple tracking system you are asking for, particularly due to the limits on the size and weight due to having to be a reasonable thing to strap on a cat's collar, or some sort of harness.

I suspect trying to make an electronic tracker of some sort will be extremely difficult, and much more trouble than it's worth.

It's been my experience that a cat generally can't get lost easily. It may, or may not, choose to come home but they are rarely lost.

Maybe he's just old enough to remember the screeching, whining heterodynes.

AM is great as long as nearly everybody else is running SSB, just like you don't really need a vaccination against most diseases, or the risk it entails, as long as most of the rest of the population has been vaccinated.

>
> (snip) Boy, this subwoofer must be so special
> that you can't just buy another one... :-)

The subwoofer is only special in that the idea of converting it scratches a really old itch. When I was overseas, there were many occasions when 110v items attracted my attention and I wondered if there was a way to convert them. And, if not, why. But, if so, how. Those questions remained unanswered.

Since I'm heading back overseas, those questions came flooding back and I decided to ask in these newsgroups. I figured I had a better chance of finding an answer here than anywhere else. But, rather than vague theory, I decided to use a real world example - the subwoofer. Yes, I know not all items are like this subwoofer, but it gives me a start at the answers. And that is really all I was after.

I'll play with this subwoofer using what I've learned here. If I'm successful, I'm that much closer to finding out what I wanted to know. If I'm not, I'll write this subwoofer off as an experiment gone bad. Either way, I have more knowledge than I had before.

Yep, I remember them too, especially 75 meters on a winter evening back
in the '50s. There's never been a sound quite like it since.

But that was all settled decades ago and Fred's still banging the drum.
Just curious why. Some kind of time warp? Didn't they make a movie
about that?

>what about the transponder idea? could that be a valid solution?

Some time back, I was noodling around with the idea of a switched reflector. The idea was to build a reflector with a switching diode which, while it's on would make a half wave reflector, and while it's off would merely present two separate quarter wave pieces which would not reflect much at all.

The idea with this switched reflector was to modulate the diode with information which would be retrievable via a Gunnplexer. This would be a low power device, it could be used to send data or to identify a target uniquely.

Using a reasonably small reflector and a low loss diode, you ought to be able to detect this unique transponder by looking for the modulation on the reflected signal. Small horns of this sort could be reasonably directive enough to play hot/cold and thus locate your cat.

Hey, I have a cat and I wonder about where he goes sometimes too. I might have to build one of these things up myself...

Hmmm... I would tend to question their claim for the distance on the ground. At least in this sort of application. For a battery small enough to mount on a cat, and to last three days, the transmit power has GOT to be fairly weak.

Take a cordless phone, for example, think about how far it reaches outside the house. Keep in mind that the cordless phone is pretty big and bulky for something to place on a cat, and it's battery is good for maybe 2 hours talk time at most.

Now take the phone and lay it on the ground, behind two neighbor's houses and a couple of cars. No way will the signal reach.....

Cell phones don't count, they 'cheat' by placing the base station way up in the air to make the signal go up and ABOVE most ground structures. The increase in performance by getting one end of an RF link at a very high elevation is well known.

==========

As regards a cat tracker, the problem is the transmitter is VERY close to the ground, and has many walls, trees, cars to go through. Not to mention the fact the antenna will have to be physically short, and horizontal. Figuring in terms of something to put on a cat, the antenna has to be flexible, and lay along the body of the cat as some sort of harness.

This means the null of the antenna has a 50% chance of pointing towards the RDF unit carried by the person. Plus the antenna will be electrically short for the frequency range which also hurts it's efficiency.

So, all in all, making something small and light enough for a cat have any efficiency while still having enough power to overcome the terrain obstacles is not easy. I suspect that it's not possible.

The alternative is to wire the neighborhood with dozens of RX units hardwired back to your house. That way the cat may be in range of one of them in spite of the weak transmit signal. This could be made to work, but expensive and complex.

Jim

I have a large power transformer suitable for a kilowatt amplifier.
It outputs 870 volts at 1.13 amps, and would deliver close to 2000
volts with a voltage doubler. I bought it years ago with the intent
of building an amplifier, but that never happened. It is a
mil-quality gray cube that weighs 60 lbs, and is located near Boston.
Please e-mail me if interested.

Thanks, Jeff N1SSV

Hi all,

I have a grid dip meter that dates back around 30 years. I decided to rip all the old guts out of it and replace the circuitry with something bang up to date. This has now been done and it works well enough, but it occurs to me that I really ought to finish the job properly by replacing the old analogue dial with a digital read-out. The problem with the old string-coupled dial is that the frequency read out is not necessarily the same as the device's output frequency; it's merely an approximation of it. To eliminate this problem, I'm intending to replace this arrangement with the guts of a frequency counter which will 'sniff' the RF from the osc and display its actual operating frequency. I can't see any snags with this idea, but thought I'd better run it past the Panel first, just in case. Any observations or suggestions?

One big advantage of the SW+ series is that there are a large number of sites that use it as a tutorial example. If you plan to build it, and learn from the experience, it is the way to go. There also seem to be a lot more of them floating around, for whatever that's worth.

Ten-Tec has been at that address for years. I have stopped by the facility
many times while vacationing in the mountains. Nice folks. What is so funny
about the address?

This book looks interesting. Is there any information as to which
author wrote which part(s)?

Source record: 37761

Hi Jim,

The 'ground' distance test was my own. I laid the transmitter on the ground, in the grass, and took off in my car, stopping every so often to listen for the signal. I have had instances where reception problems occurred at .8 miles. The transmitter was laying in a furrow in a field. The beacon is a .1 second pulse every 1 to 2 seconds.

I used this tracking equipment in my high power rockets. I became a little upset with loosing $300 worth of equipment every time I lost sight of a rocket.

I tried a various 2 meter setups (CW), but none seemed to match the performance of a falconry tracker.

I do not use the equipment anymore. The feds are really clamping down on high power rocketry as a hobby. I broke a altitude record and went back to work programing computers and playing with electronics.

Regards

Yes. Wes wrote chapters 1 through 7 and large parts of chapter 12. Rick wrote chapters 8, 9, and large parts of 12. Bob was the primary contributor to chapters 10 and 11, and wrote a section in chapter 12.

This is from the "About the Authors" section at the front.

This may be a solution.

A guy involved in Mountain and Bush Rescue (NZ) has devised a system to locate lost, missing or injured people. The Rescue people use dogs, which is a highly successful method but sometimes the dogs find the victim but are unable to get the rescuers to the spot. Does the dog stay with the victim and try and attract the rescuers or go back to the rescuers and try and retrace his track as he (the dog) can't actually give them a location ie: doesn't know the postion and cannot talk.

What they have done is make a coat for the dog that has a locator beacon (Transmitter) and a GPS in special pockets. The dog handler sends the dog off with the GPS on, and when the dog finds the victim he (the dog) is trained to pull a tag from the pocket. This does two things (a) the Locator beacon is attached to the tag, and is turned on when pulled out, the dog drops this by the victim. This can be located with a directional antenna and receiver. (b) This is the clever part, when the dog pulls the tag and beacon out, this also triggers the GPS into marking a "waypoint" at the spot. The dog now retraces his track to his handler who can now see the dogs track on the GPS and the victim is at the waypoint position. They can now use the "retrace track" function of the GPS to get to the Victim. They can also use the beacon to further aid location.

One could get the smallest and lighest GPS that has a track capability and attach it to the cat, and when it returns have a look at track log. Can even be displayed on some PC GPS mapping programs in real or accelerated time. I use Oziexplorer, a really excellant program for the cost (I have no connection with product, financial or otherwise, just a satisfied user).

==========
Rich , I do have a new ,'never used' Microwave Modules 144 MHz to 28 MHz
converter with output for a transverter.
Since I recently acquired a 144 MHz and 430MHz transverter for an existing
HF transceiver , I no longer have a need for the MM converter.
If you are interested ,please let me know

Try http://members.lycos.co.uk/spectrum/

They may have just what you need.
E.g. http://members.lycos.co.uk/spectrum/amateur.htm#RECEIVE_CONVERTERS

I have a 6 to 2(IF) transverter and it works well. They do receive only ones.

Well, he should have had a torch.

What would be wrong with an L.E.D.,pulsed to flash every few seconds and two
pairs of eyes and the locating device, one to say "There he is"" and the
other to say "But you can't go in someone else's garden!" ?
Regards, G.H.Ireland.

I don't know if it's still in production, but Tokyo Hy-Power used to do a
5-band transverter, i.e. 80, 40, 20, 15 and 10 from a 2m exciter. I don't
know if they currently have an importer, but I understand they are happy
to send equipment to customers direct from the factory in Japan.

>it stands for Antisocial Modulation.

Current solid state technology allows PWM rigs to have an overall
efficiency percentage in the mid 80's.

Used with a decent limiter there's no reason to cause anyone
interference.

Try it sometime, you may like it.

$16 per box of 4000 or

4,000 680 Ohm, 5%, 1/4 Watt Carbon film resistor, $2 per 100,
$16 per box of 4000 or

My e-mail: centralub@yahoo.com

Minimum purchase $5.

No shipping is included in the above prices. To quote you a
total including shipping, I require your full ZIP code or
postal code in addition to a list of what you are interested
in. Please specify the country for international orders
outside of North America.

The only part that I will ship for $3 to anywhere in the US
and Canada are the 100 packs of resistors. So a pack of 100
resistors is $5 inclusive shipping.

All electronic parts are new. All semi-conductors are stored
in anti-static tubes/bags or on anti-static foam if you purchase
less than a tube/bag. Below is the complete listing of all parts.

Offers on the lot are welcome. Keep in mind that I am looking
for a price below wholesale, but more than the commercial buyers
of surplus electronic parts are offering.

I've done this with a separate link and a sensitive counter, and
it IS nice to know the 'real' frequency. Nice when you're using it as
a poor-man's signal generator, too.

Since you're inside it, just add one more FET follower and
a cable output, with a small but unchanging coupling cap.

very well, but since it is so many sites where the conventional
constructions are repeated, I want to show something different. Most
home-constructors have a signal generator, usually quite accurate, and
it is no reason not using this instead of building a new GDO and have
to calibrate it - complete waste of time and ressources

I know; I've spent my life in the biz. The last 600 kW I built had an overall efficiency of over 83%. But it was for broadcasting, not amateur communications.
>Used with a decent limiter there's no reason to cause anyone
>interference.
I wonder whether the use of the word decent was a Freudian slip since the use of "Antisocial Modulation" at this stage of the hobby is a decent into a world of excessive bandwidth and low transmission efficiency.

Yes that is exactly the way it is supposed to work. Radios of this
generation actually showed the difference between the 800hz received tone
and the transmit frequency. In newer radios, the manufacturers have
programmed them simply to show one frequency. Apparently they feel this is
less confusing.

Indeed? And how do you propose getting a decent 'dip' from a
conventional signal generator? Their output impedance simply isn't
high enough.

I would be curious as to a good answer to this also. It is hard just to find some amatuer activity on Greenland. Data, what type of data do you want to transfer? 300 baud lowband amtor, or similar is going to be the extent of 'live' data transfer. So much for that 30 megabyte file hehehe. Greenland does have some internet transfer capability (mostly via satallite telcom links). Would be nice to find some M.A.R.S. operators on a regular sched though!

Either connect BOTH gates together (mind the input C) or ground gate 2
and use gate 1.

There may be some advantage to connecting gate 2 (bypassed to ground with a
suitable capacitor) to a positive bias. (depends on the fet and the desired
operating point).

1205. need spec sheet for CA3035

Shouldn't that be "diode from Output to Input" ?

Normally a crystal set can't recover enough signal to drive a speaker directly no matter how you try and match the speaker to the radio. Even if you had a speaker with a 2000 ohm voice coil (actually a headphone element attached to a speaker cone) there wouldn't be enough signal to hear very far from the speaker.

OTOH if you live near a local am transmitter the signal can get quite loud. In fact that may be the ONLY station you hear. I used to live a few miles from
a 5KW am station, and it's signal WOULD drive a small speaker from a crystal set. (If I lived any closer, the signal might have driven a small CAR).

Hehe! I once lived about 4 miles from the BBC World Service (600KW
output). I built a crystal set as a kid, but this was the only thing I
could pick up on it. I later discovered that you could actually pick
up this station on just about anything, due to the intensity of the
signal strength at that small distance. Even ordinary household
objects would start acting as detectors on some days!

I have a tek 454 that I won at a company auction where I used to work.
They were
getting rid of some older equipment and decided to give the employees a
chance to
buy them. No minimum bids, but they did suggest what they were worth.
I got the
454 for $150, and when I went to pick it up they 'threw in' a scope
cart, a viewing hood,
and a half dozen probes.

They also were auctioning off a 465, but I was told that the CRT in the
465 didn't last, the ones
in the 454 did.

> K6hm

I have even connected a pot from the output lead to ground and connected
the common lead of the regulator to the wiper of the pot and used 7805's as
adjustable regulators. The trick worked just fine, only problem is you
can't
go lower than 5 volts (lm317 only goes as low as 1.2 volts). You don't want
to exceed the input voltage rating on the 7805, but I think it will go

as high as
12 volts output without exceeding the input rating.

>
> Bill, WD5HHH
>

I was thinking of a design for an all band receiver too. The design I'm thinking of would use a first IF in the 6 meter band (variable if) so it would
be an up converter working into a 6 meter receiver. Second if would be 9mhz (I found a half dozen if filters with an 8 pole shape and a bw of 3.2 khz at Dayton
a few years ago. Would use at least two of them in the if). Third IF would be
either 455khz (also have a few Collins mechanical filters in the junk box, one
with a 2.0 khz bw, one at 2.7khz) or 85khz (BC453 cans.) If I use the 85khz
if's the stage will use a 6AR11 tube!

1219. RF Trans Identification?

Newsgroup: rec.radio.amateur.homebrew

Hello All,

Got 3 RF transistors. Looking for specifications. Google, no help!
Don't even know if they ever made it to "production".

Marking:
Motorola "BatWing"
SRF3131
SAMPLE
102

Package:
6 lead - 3/end B-C
Square ceramic cap, ~0.4" / side.
Rectangular flange, ~ 1" x 0.4"

My ohm meter suggests, at least, they are bipolar...

Thanks es 73,
Woody

If you use G1 as the input, G2 voltage will affect the gain. Ground
for minimum. To raise gain, bypass well to ground and apply bias.
Depends on device, but if the Vds is 4 to 8 volts, 3 to 4 volts will
go to near max gain.

When I tried Mntty thru the soundcard I was able to use the same interface that I built for digipan. Check out the digipan docs, that shows you how to interface a radio to a sound card. Digipan, Mntty, Cwget and Cwput all use the same interface, the only one that is different is the slow cw program whose name escapes me right now, it used a different pin to key the transmitter, but in that case I just made a null modem style pin swapper that I would add when using it.

As long as you have a mic in, spk out, and a serial port on the computer you have all you need there. On the computer end you just need to locate mic in, spk out and ptt.

The interface I built used 2 audio isolation transformers, 2 transisters, a couple of resisters, and maybe a diode or two. Took all of 10 minutes to wire it up on a perfboard.
thanks, John.

Thanks for the replies & emails...

Unsure of original source... They are multi-hand-me-down goodies.
The ohmmeter sez there are "diodes" in the right places, so some die
is there. Searches come up empty. As commented (unless I got damn
lucky ;), they will likely remain a mystery. Too bad, the pakage
suggests a nice power level - somewhere...

Tnx agn,
Woody

Ah, but then you would only be able to listen to media that was recorded in an
audiophile-quality studio, using all of the above dreck..
Since i know of no studios that meet the above specifications, I guess they
will have to listen to the blissful silence.

And don't even think about listening to live recordings, since none of the
pro audio companies use the above listed dreck on the road..

Looking for one new or used but working BLY92A.

I cannot find an exact substitute, either the package or thread/stud is
different or the electrical parameters are way off base.

Any help appreciated.

hi there

building a vhf amp as a driver for a bigger amp to be installed in a band 11 tx. (for use in Africa.)
now I need 100-150watts out and I have some sd1407's....
I know these transistors will work here frequency wise but am unsure of power out and gain at 108mhz.
So far I have managed to get 80w with 15 drive at 28v in class C, about 7db gain..
Any thoughts????
Has anyone used these devices??
I assume they are ment to be used in class C at VHF?

I have been told they are good for 150w are they??and if so does anyone have a tried and tested design..?
The spec sheet of course doesnt mention vhf use..

thanks Simon

The "S" in this case stands for special. When Motorola run a batch of RF transistors... they are sorted by various characteristics as to performance. The "S" on this type of device signifies espescially high gain.

The other news I have is that I have been unable to find any information on that device number...

1244. TCA440

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-18 00:14:49 UTC
From: Petar Ristic <rileso@eunet.yu>
Message-ID: <b2rslh$3n7$1@news.eunet.yu>
Source record: 37697

Use TCA440 as secondary mixer from 10.7MHz to 455Khz and IF amp, voltage at pin 11 is 1.1V, pin 12 0.1V and pin 13 0.1V. They would be 1.5V...
I know that, without schematic, is hard to answer, but I interest which pins have influence on bias point of this pins???

Thanks!

You must be joking, OM.
2m 15W 28V standard SOT48 case shouldn't be difficult to find.
Motorola replacement is 2N5641, while replacement for BLY92C is
2N5642, so I would check up the data for for the latter device

Could pass you few pages from the Philips handbook on an occasion

There was one in "Electronics World" March 1994 in the Circuit Ideas
section.

The detector is similar to the one in the link in the other posting
but it uses an op-amp to increase snsitivity. Works from 100kHz to
500MHz. If you're interested and can't find the issue let me know
(email) and I'll post it somewhere.
Regards.

Hello Paul,
just the same as a crystal set with a meter.
No battery, metal box, telescopic aerial, germanium
diode, nice big meter for viewing at a distance.
I sit mine on a household metal serving tray that has
been around for decades and not likely to get
chucked out, helps getting consistant readings.

Is this meter for your radio controlled fighting
robot project?
How is it going?

Regards,
John Crighton
New South Wales

John,

found it. Brilliant - many thanks.

I did try the On Semiconductor (the new name for Motorola
Semiconductors?) web site. I found a reference but not the document. I
didn't think to try the Motorola web site as I thought they were now
different. Confusing.

regards...

Off topic i know but ...

I've always wondered why it's always been said that ssb (or dsb) has no carrier.

Cuz it does, it just aint their when no modulation is present, take the carrier away completely and you no longer have a transmitter ... hehe

anyway, carry on guys, sorry to poke my nose in :)

I have a copy of one that I've built. It works for checking FSM as well as using it to test for very small RF voltages in a transmitter when tuning or repairing. I've built two of them employing other options of my own and they have saved me hours of time already. Cost about $10 and an hour to build. Depending on parts on hand and how you choose to build it. This is a non tuned meter... can be used over a pretty wide range.

sniff a ssb with a scope, you'll see a carrier modulated by the envelope, you have got to have a carrier for it to propergate thru the ether, just not modulated in the same way as AM or FM.

Sniffed it many times, there is no carrier. Just RF in the form of a
sideband. You're misunderstanding the definition of "carrier".

A carrier is a more-or-less constant RF signal which has its properties
changed by some form of modulation, typically AM or FM. The total signal
transmitted consists of the carrier and one or more sidebands. With SSB,
the carrier and one of the sidebands are removed and only the remaining
sideband is transmitted.

Here we go.

AM is actually a translation of audio up to radio frequencies, in
the same way that mixers in superheterodyne receivers translate frequencies.
The carrier is needed, to beat against the audio information and create
the radio signal.

You've got a 1KHz tone, and a 10MHz carrier. Mix those two together,
and you get a signal of 10.001MHz. You also get the other sideband, or
image, from the difference, 9.999MHz. Each are radio frequencies, just
as real as the 10MHz carrier.

That 10MHz carrier is there as a result of an imperfect mixer. It
servies no purpose at the output of the mixer, just at the input.

Use a balanced mixer, so there is no feedthrough of the carrier,
and you get the two sidebands, 9.999MHz and 10.001MHz, which because
of the simple modulation signal, are two distinct radio frequencies.
They transmit fine. And since each are mirror images, you can even
get rid of one, so you have an SSB signal.

At the receiver end, you are translating the signal down to audio.
With an SSB or DSB signal with suppressed carrier, you have to insert
that beat signal at the receiver. With SSB, that's the role of the BFO;
with DSB it's a bit more complicated but the same principle.
10.001MHz-10MHz, and the result is your 1KHz signal again. Note
that without that reinserted carrier, you cannot recover the original
signal. You can see the amplitude variation of that original signal,
but can't actually demodulate it.

With AM, since the carrier is still there, you don't need to
reinsert the carrier at the receiver. The carrier signal sent
out of the antenna mixes with the sidebands in the receiver's detector,
and the sidebands are translated down to the original audio frequencies.

aye I know the 'carrier' that's actually transmitted is not the original CW carrier that's fed into the mixer, but it's still an RF carrier when it comes out tuver end, just a mix of modulating waveform and original CW carrier. Though spread across one side or the other (or both) of the original CW.

The word 'carrier' to me means the actual sinusoidal AC waveform (at RF freqs) that has the modulating waveform piggy backed onto it and 'carriers' it thru space as it were. Whether it's a side band (mix of original CW and modulating waveform) or not I wasn't discounting, was just saying.

Thing is the CB craze has created so many inexpensive 10M rigs that converters are less than popular. You can usually buy a Radio Shack all-mode 25 watt rig for well under $100US on ebay.

>substitute, and retune your matching a bit.
I think you're most definitely right.

I have a TP9383 winging it's way to me from Holland as we speak. The
driver device seems to be the problem. The BLY92A

I've been unable to find an online datasheet.

My requirement is to replace the missing parts (driver and output) in
an old Rohde & Schwarz FM broadcast exciter that runs around 60w out.

Here's as much spec as has been passed to me:

BLY 92A
sot 48/2 15W, 8-32 UNC 8.5 mm diam nut 4.2mm clearance mtg hole

(((73)))

The original continuous wave RF carrier is suppressed
anywhere from 30 to 60 db down depending on equipment.
That much suppression is essentially "no carrier." There
is seldom enough amplitude there for effective detection at
the receiver. The receiver must supply a local RF carrier
very close to the original, suppressed carrier to recover the
original modulation information.

>Cuz it does, it just aint their when no modulation is present, take the
carrier
>away completely and you no longer have a transmitter ... hehe

Incorrect even to popular simplistic newsstand publication
standards.

Sideband content is at RF. Sidebands of AM, FM, or PM
carry the content of modulation and their transmission follows
RF propagation rules.

With standard AM (as in broadcasting) the carrier is
necessary to mix (heterodyne) with the sideband content
to derive or demodulate the modulation content in simple
detectors such as a single diode. Such simple detectors
are a form of mixer, mixing the carrier RF with the sideband
RF, suppressing the sum components, passing only the
difference components. The difference components are
the same frequency and amplitude as the original audio
used for transmitter modulation.

More complex detectors (e.g., "product detectors") use a
local RF carrier source to substitute for the suppressed RF
carrier. The action of demodulation is the same, heterodyning
and passing only the difference mix products.

The original "SSB" used in communications was frequency-
division multiplexing of four voice bandwidth channels
(approximately 3 KHz each) over an approximate 12 KHz

total bandwidth. This is typified by the old "Type C" carrier used in old long-distance telephony in the USA; Brits have something similar. A "pilot carrier" may or may not have been sent and used only for locking/stabilizing the receiving end carrier substitution oscillators required for demodulation of higher audio channels.

The first RF SSB used modulation almost directly from the telephonic "carrier" equipment. That began about 1930 and both governments and commercial carriers were using that form of SSB for the next five decades plus. Four voice bandwidth channels but two of those voice bandwidth channels were usually devoted to AFSK teleprinter (now lumped under "data" group in USA regulations). Six to twelve TTY circuits and two voice circuits could be sent on the same radio path from a single RF transmitter. The end result for TTY was four separate levels of frequency translation: DC loop current converted to audio tones, those audio tones frequency-shifted for several tone pairs (of separate circuits) in one voice bandwidth, several voice bandwidth channels frequency-shifted again to multiplex them within a single wider-bandwidth audio range, then that wideband audio frequency-shifted to RF for the actual SSB transmission. Everything winds up as RF with a relatively-narrow bandwidth on a radio path...then is demodulated to the original at the receiving end.

Some amateurs confuse the original SSB with the single-channel SSB that started becoming widespread in the late 1940s, first with military communications, then spreading to amateur radio, maritime radio (particularly boats and small ships), aviation (for long-distance comm), military radio (particularly for portable HF use on land, needing less local primary power demand). For single-channel SSB the prime requirement at each end is tuning frequency stability since very few such systems have "pilot carriers" for synchronizing/locking the RF carrier substitution in the receiver. Quartz crystals for frequency control were essential to make single-channel SSB viable for many different radio service applications. That came about after WW2 which spurred the large growth of quartz crystal unit production.

The very first "SSB" was in land wireline long-distance telephony. The first RF SSB was an extension of that long-distance telephony. Single-channel SSB became popular after WW2, having obvious advantages over conventional AM but absolutely needing frequency stability of the carrier or reference frequency at both transmitter and receiver.

>anyway, carry on guys, sorry to poke my nose in :)

You got a lecture. If your nose bothers you again, please
consult a physician. :-)

The problem is, if you have any interest in communicating with other people, you need to use the term "carrier" in the same way everyone else does and has for the past hundred years or so. If you don't know what this meaning is, it would be beneficial to do a little research and find out before you use it. Of course, you're free to use any word to mean anything you like. But making up your own definitions sure interferes with communication -- if that's your objective.

Did you know pigs fly?

The word 'pig' to me means a feathered creature that lays eggs and chirps. . .

Hello Paul,
here in Sydney, every Saturday morning, one of my vices
is looking at other peoples rubbish from garage sales or
yard sales. Looking for bargains in ordinary householders
front or back yard. Do you have that sort of thing in the UK?

Anyway, you can always pick up some kids abused
and discarded radio control cars for a few dollars.
The receivers and transmitters are usually poor quality
but servos are usually quite good. You never no
your luck and may come across some broken
good quality stuff that is at a near give away price.
The idea being you are buying cheap because it
is broken and you can use your skills to repair it.

With the field strength comparison tests. I used to
borrow my friend's good quality Futaba transmitter,
note the meter reading, then replace his transmitter
with my home made one in the exact position.
Your hands will make a difference, holding it or not.
Same with the field strength meter. All very frustrating.

This Sunday, in Wyong, New South Wales there
is a big amateur radio field day with a buy and sell
of new gear and loads of old stuff from trailers and vans.
I always come back with too much junk. What I am
leading up to tell you is, that these ham get togethers
are great places to buy old pieces of test gear.
Have you got a Sig Gen, CRO, frequency meter?
For example I picked up a nice Marconi 144h
Sig Gen for a friend for $10. The attenuater
was stuffed and a few other things were dud
but old gear like this is easily repairable.

I know you have building a GDO. I have seen
nice ones quite cheap at the field day. If you start
making every item of test gear sometimes you lose
sight of the main objective.
That happened to me with my car rust repairs.
I wanted a tig welder, they were too expensive, so I
decided to make one. I got so involved in building
the welder that I almost lost interest in fixing the car.
In fact, I have still to put the mudguards back on the
little van and get it ready for the trip to Wyong.
All good fun, keep us informed of the robots progress.

Regards,
John Crighton
Sydney

Suppressed the main carrier may well be, but the side band(s) aint, and that's where you'll find your resultant carrier(s) :ï¿½)

Lecture or no lecture, you must always have a carrier as the basis of an RF signal, whether it's fixed freq or distributed in the side bands, it's still a carrier :<)

Why are you guys getting so upset, have I offended anyone ?

1281. New SXList.com Design Contest!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-19 01:22:12 UTC
From: Josh Koffman <listsjosh@3mtmp.com>
Message-ID: <3E52DC44.44BAF465@3mtmp.com>
Source record: 37728
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.model.rockets

Hello all. I'm extremely proud to announce the opening of a brand new SXList.com contest! This contest is amazing, there are tons of prizes, and entering isn't that difficult. There are three main categories, and one basically just involves adapting code to the Scenix chip. If you've had an idea for a microcontroller based project, why not check out the Scenix chip? You could win great prizes!

The contest is focused on the Scenix microcontroller (a PIC compatible unit that offers up to 75MIPS). Have an application that needs blazing speed? The Scenix chip is easy to get into and offers tons of speed. By just coming up with an idea, you may win all the development tools you need to put it into action!

If you wish to pass this information on to others, please feel free. The contest is an excellent opportunity for beginners and experts alike. And everyone benefits by the addition of SX examples to the web library.

For complete contest details go to http://www.sxlist.com and follow the Design Challenge Contest link. At the end of this post will be the official release.

Enter soon, and enter multiple times! We look forward to your submissions!

Thanks!

Josh

A common mistake that people make when trying to design something completely foolproof is to underestimate the ingenuity of complete fools.
-Douglas Adams

SXList.com 3 WAY WINNER CONTEST

There is a new contest at sxlist.com! And this one has 3 ways to win! Are you a HARDWARE wire head? A SOFTWARE guru? or are you the IDEA person? Anything is ok! You can just send us a good idea, or share a circuit or (learn?) PCB design, or show us some cool code.

Prizes will include SX-Keys, SX chips, SXWiz BASIC to ASM code generator, Ethernet demo boards, RS232 level converters, and your name in lights on SXList.com!

In the past, I've set the focus on nearly finished projects (code ready to debug, design finished, etc...) and we have received some really nice

entries...

http://home.attbi.com/~andrew.g.miller/sx-x10/ The SX-X10 Internet Home Automation Remote Control.
http://www.sxlist.com/lib/io/dev/video/servid.htm The SERVID 4x20 bit banged video terminal.
http://www.sxlist.com/contest/reverb Digital audio reverb and echo effects box.
http://www.sxlist.com/contest/sxohm SX PBX On-hold messaging switch
http://www.sxlist.com/bindicator Bindicator remote display
http://www.sxlist.com/contest/aquamon SX Aquarium Monitor (in SXWiz BASIC)

I'd like to move the focus to a slightly less demanding contest and offer several different points of entry:

A) Ideas that match the SX chips well: What application can you think of for which the SX chips are a perfect fit? Something that could be done in a PIC except for the lower clock speed. Something that needs THROUGHPUT (or that involves doing a bunch of slower tasks all at the same time so that one SX could replace several PICs) but doesn't need a lot of RAM or a huge amount of code. An application where the power supply can support the high speed requirements. Here are some examples: http://www.sxlist.com/idea/sx.htm

B) Great Circuits or Printed Circuit Board Design. Have a really killer little circuit that involves an SX? Then you have an entry! But I want to encourage another path here as well: Right now, AutoTraxEDA is GIVEING AWAY the current (first) release of their professional PCB design software: It supports Mult-sheet schematic entry, circuit simulation, rule driven PCB layout, fast autorouting, 3D visualization and Computer Aided Manufacturing tools. WOW! They will be charging for it at some future date, but for now this is a fantastic deal for the little guys. http://www.autotraxeda.com/Purchase/purchase.html

Co-incidentally, a PCB manufacturer is giving away PCB panels in return for posting a public design using a compatible processor. SX is ok. See: http://www.sxlist.com/piclist/pcbcontest These are limited to double side, 160x100 mm, solder mask, component print and must follow the guidelines posted at http://www.olimex.com/pcb/techinfo.html but you get an entire
panel free and the quality is great! So... Design a PCB using an SX, if you haven't done one before, this is a great opportunity to learn and you can get a fantastic design program FREE. If you win, I'll throw in one or more of the prizes above in addition to your PCBs.

C) Code snippets: Any bit of code that does something better, faster, or that hasn't been published already on the SXList.com site. If you can't publish the entire project, but you have one part that you are especially proud of, share it (and let the world know who you are). Lots of people have published something on sxlist.com and been amazed at the number of questions, thank you's and even, sometimes, yes, actual paying

jobs! Come on! You've figured out something that you're jazzed about! Show us what you got! Just starting? No problem: Browse the PICList code library http://www.piclist.com/lib or PICList archive and find some code that you would like to see in an SX. Use the MPASM to SASM code converter:
http://www.sxlist.com/cgi-bin/mpasm2sasm2.exe and then check for any warnings and clean up the code for the SX.

The prizes are nice, entering is easy... I expect to be overwhelmed with entries! Use the little form at the bottom of the webpage to describe your entry and/or send the files to JamesNewton@sxlist.com

Well Clive, let me take a stab at it.

Others have described SSB operation and AM operation superbly.

You will see some elementary explanations of how AM works by
describing the "carrier" as "carrying the modulating or voice
frequencies". It was a simple way of describing an AM signal.

The word "carrier" is really a misnomer. The "carrier" doesn't really
carry anything. In an AM signal it just happens to be present with the
two side bands. All independent of each other as far as propagation
goes.

There is only one meaning of "Carrier" that I am aware of when talking
about a basic AM or SSB signal. Any information or signal in a side
band is not referred to as a carrier or having a carrier.

Each RF frequency stands on its own and propagates all by itself
regardless of what else is present or not present in the composite
signal. One signal component does not need any of the other signal
components to get where it is going.

This is true :)

Clive

1285. Overtone Xtal ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-19 05:51:51 UTC
From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <v566rpdjnoiv89@corp.supernews.com>
Source record: 37738

I have a deaf HP 8590A spectrum analyzer with no Cal. output and this may be the reason for deafness because I'm told that a mixer frequency is derived from the same oscillator. I don't have a manual, schematic, block diagram or extender boards. The Calibration frequency is supposed to be 299.9MHz and comes from the A9 board. The A9 board has a half height TO-5 cased xtal in a 2N5971 circuit and as best I can tell the xtal is connected to the emitter. With the A9 board out on the bench and using my Kenwood DM-81 dip meter I get a good dip at approximatley 30.5 MHz. I'm not sure if this is the fundamental or not but if it is they must be using the 9th overtone, does that make sense?
I have an old HP 141T with a 8553L and I jury rigged a small probe that I could snake into A9 thru a cal hole and I could barely see a blip around 10 Mhz and 26 Mhz. Not sure of these frequencies because I didn't write them down and it's late. Then I connected a piece of wire wrap wire to the base of the transistor that is fed by the 2N5971 and again I could see a couple of very weak signals that I know where coming from A9 because I turned the 8590 on and off. And this is where it got interesting. When I turned the 8590 on, for a short period of time I could see a nice blip that decayed in about a second. I'm guessing that the overtone crystal is lazy, cracked, or some associated circuit component is bad. There are 2 adjustments on the board that I haven't touched, a trimpot for amplitude and a coil slug for frequency. The coil is 4 turns on a 3/16" core. I haven't turned either but am tempted to. (A couple years ago I bought a non-working Racal 1992 counter and I found that the OCXO had no output and after checking everything and finding nothing wrong I gave a slug a turn and it came to life. As best as I can recall Racal derive 10 MHz from 5 MHz but this wouldn't be overtone. But I had the service manual and had less fear of turning slugs).
I've not had an experience with overtone oscillators and am looking for help. All suggestions appreciaed.
tnx
hank wd5jfr

>here in Sydney, every Saturday morning, one of my vices
>is looking at other peoples rubbish from garage sales or
>yard sales. Looking for bargains in ordinary householders
>front or back yard. Do you have that sort of thing in the UK?

We do indeed. We call them "boot sales" because householders typically
turn up with a boot-full of their old curiosities. BTW - an aside to
our American chums - "boot" in UK = "trunk" in Americanese.
Problem is, they're almost invariably on a Sunday mornings and start
at some obscene time like 6am. I don't get out of bed on Sundays until
my hangover is gone, so that's usually getting on for noon. Sadly I
don't get to frequent any boot sales. :-(

You're absolutely right, but all the hamfests seem to be in the north
of England and a good 100+ miles away. I don't suppose that seems like
much to you, but us Brits it's like the other side of the world!

> I know you have building a GDO. I have seen
> nice ones quite cheap at the field day. If you start

I find exactly the same problem, too. But now I'm finally wise to it,
I find I don't lose the plot so easily. But you're absolutely right:

these diversions can be perilous!

Message-ID: <Aj_4a.170510$iG3.21205@sccrnsc02>
Source record: 37746

FORCED AIR COOLED TETRODES....

For Sale 4CX-250's brand new in Military Cartons and Canisters.Standard heater voltages not Military Only. Some B,R and FG models. In addition We also have some 7034 models as well.

They are not your typical swap-meet prices but if you want quality and functional products we have them. And their not as expensive as buying them from many of the main suppliers.

We have about 12 pairs left in inventory now and they are not going to last much longer and it will probably be 90 days before we can get in some replacements. Supplies are getting more difficult to find as time goes on.

In addition, we have some USED TUBES as well. We do have some that have low hours on them and some pulls but they are all functional. You must test them within 14 days of receiving the unit/units. We cannot be responsible for their operation if you keep them on the shelf for 3 months and then tell me they don't work. If you are not satisfied with our products you pay to return them to us, and you will be refunded the cost of the tube/tubes.

Shipping and handling costs are in addition to the price of the tubes and will depend on your zip code. Shipments CONUS only. Insurance is advisable and is available if you request so at the time you place the order.

Please serious inquiries only.

VALVES R US.

From: Bjorn Henrik Vangstein <no.sp@m.no>
Message-ID: <IO45a.30141$Rc7.428923@news2.e.nsc.no>
Source record: 37598

I have an old Yaesu FT-277 which I use as a mobile rig. But I have a problem with the LF-stage. Some time (5-10 minutes) after I have switched the power on, the speaker sound nearly disappear - it's very weak. Instead I hear some weak locally generated sounds and after some time (from some seconds to several minutes) the sound level (with a sharp and loud click) comes back to normal. I believe that the problem is that the circuit on the LF-card goes into self oscillations. Does anyone have some tips on how to cure this problem?

1296. High performance antenna tuner

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-20 14:34:58 UTC
From: Heinz Bolli <heinz.bolli@hbag.ch>
Message-ID: <3e54e710$1_3@news.bluewin.ch>
Source record: 37599

Hi all

We are constructing a new antenna tuner/matchbox especially for symmetric antennas. The most important featueres will be:

- Matching of symmetric antennas
- 1.8 to 30 MHz
- High impedance matching range, capability for compensation of high reactive loads. (50 Ohm to up to 3000 Ohm +/- 3000 Ohm reactive)
- High power handling (up to 2 kW)
- Remotable and/or automatic function
- Working in Transmit- AND Receive-Mode (with ICOM-Transceivers)
- Matching unit for outdoor mounting (near antenna feedpoint)
- Control unit for indoor use (near Transceiver)

We are looking for techincal interested amateurs for broad field tests. We offer a absolute high quality unit from our pre-series for a fair price.

Interested? Then contact immedialtely:

1297. Doppler Radio Direction Finder - Ramsey DDF1 kit

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-20 15:18:09 UTC
From: cwolf01@attglobal.net
Message-ID: <dfcb9d69.0302200718.1297adba@posting.google.com>
Source record: 37600

After reading the QST May/June 1999 article, by Mike Kossor WA2EBY, on Doppler RDF; I'm interested in purchasing the Ramsey Doppler RDF kit (DDF1). Ramsey's catalog says that the kit is based on the WA2EBY design.

Does anyone have any experience with performance of the completed kit?

How does it compare to other D-RDF designs such as the Roanoke?

There also is a "kit" available from Mouser Electronics. Does anyone have any experience with this "kit"?

Thanks -73-

AM-6155/GRT-22 FAA Surplus Linear power amp, Specs: 225-400MHz, 50W out (conservative) 10W in, Eimac X651Z/8930 final, extensive metering, can be converted to 2m, 220 or 432, rack mount 7" high, 80 lbs, ITT (model 3212), Part of AN/GRT-22. This Amp uses Emiac X651Z/8930 in silver-plated cavity-drawer; 175-turn TUNE counter dial. Main chassis has solid-state power supply and buffer amp/mulitplier; panel meter monitors voltages. Requires 105/120/210/240 VAC 50-400 Hz and +20 V req 60 ma. +20 V keyed; 7x19x18.5, 80 lbs shipping weight. The HV Supply from AM-6154 is Loaded with GREAT parts to include a 1752V at 270ma transformer, 8HY 300ma choke, 100K ohm 95 watt resistor, 2x5mfd 3KVDC capacitor, & rectifier circuits card. Most hams use these amps as a 2m or 220 Mhz or 432 Mhz Linear. After conversion, the output power is approximately 400 watts. One ham has used a 4CX400A (available from Svetlana)to raise the output power to 450 Watts. Do a Google search of AM-6155 and you will find many references to conversion information. Used - Excellant Condition (NOT TESTED) but sold AS-IS.. Email if you have any questions. Buyer will pay shipping (approx 90 lbs) from zip 31088 and a packing charge of $20.00. I will ensure the item is packed to survive the trip!

1301. FM radio microphoney

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-20 23:29:05 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <3E55657B.CB8AAE44@alma.demon.co.uk>
Source record: 37604

I'm working on my second 6m FM receiver. It's based around the Motorola MC3362P device. With a simple coil change I hope to try to get it working on 2m. The receiver has been built on a single sided PCB with flying leads to attach to the synthesisor control chip (MC145170P). Tuning is accomplished via a PIC based micro with keypad and LCD display. An external amplifier was connected.

I tuned into a transmission but found that if I tried to increase the volume there was horrible audio oscillation. I also noted that just touching the circuit with a scope probe caused an audio response from the speaker (it is remarkably sensitive!). Eventually I tried lifting the speaker up from the desk and holding it away from the circuit and I was able to crank the volume control up higher. So I now suspect that the microphoney problem was causing the audio oscillations.

I have tapped various components, even though there aren't many in this circuit. My suspicion falls on:-
1) the 10.245MHz xtal
2) the tuning coil (but it is wound on a plastic former and coated with laquer)
3) the 455kHz demodulator IF coil (the metal case is grounded)

If I hold the above components manually the microphoney problem is still there.

Any ideas as to what might be causing this?

regards...

--Gary

You ought to look at the Bliss Automatic Balanced Antenna Tuner.
http://airwaterkinginc.purification.com/bzmmremotemotor.html
It will be a strong competitor. Let me know if your price point is
significantly less. Palstar also offers a Balanced Tuner, but not
an automatic one.

Hi Group,

I have a Wavetek unit that has what appears to be a shorted cap in one of the modules. I need to remove the module to get inside it. Looking at the bottom, it appears that the module is held in place with a screw and something that looks like a stand off.

Question is how to get the module out, if there are anything I would look out for while removing it.

Thanks,

Paul

Source record: 37612

Still in time to revive this thread, I hope... I was browsing through the newsgroups looking for information regarding frequency mixers and run into the thread. Although my application is not related to radio, this is probably the place to ask, people here seem to have a great deal of experience with mixers.

I have one of the aforementioned SRA-3 mixers, and have found an unexpected behavior in my test configuration: right now I am just testing it to determine noise levels and see what the best conditions of operation (RF and LO power, etc) are. Of course these parameters are given in the specs sheet, but it is always a good idea to get familiar with new devices, and I am completely new to mixers.

Anyway, I am testing the mixer at 10 MHz (the frequency at which I'll have to work) by just using two function generators to send two sinusoidal 10 MHz signals into the RF and LO ports. The signal levels are just slightly below the ones recommended by the manufacturer for linear operation (+1 dBm for the RF port and +7 for the LO port for a 50 Ohm load). The two signals I am sending in are not exactly of the same frequency: they differ by a few tens of Khz, so at the IF output I expect to see the higher order sideband (around 20 MHz) and the lower order one (these tens of kHz) together with some 10 MHz leakage from the LO and RF ports, and perhaps some higher harmonics.

The IF port is terminated with a 50 Ohm resistor to ground, while the RF and LO signals come directly from the generators into the ports without further filtering or attenuation (I am using 50 Ohm coaxial cables about 1m long). I tested that both generators have no problem to give sinusoidal signals of the required amplitude into 50 Ohm resistive loads (just by using the 50 Ohm input of a scope). All the grounds of the mixer (the three ports plus the case ground) are tied together.

What I observe in this configuration is that when I connect the sinusoidal signals to the RF and LO ports both waveforms experience a great deal of distortion: they get flatter at the peaks and seem to show higher frequency ripple. I have measured this with a 1 MOhm scope probe to avoid perturbing the system. The output at the IF port has the right frequency components, the two expected sidebands plus a little 10 MHz leakage, but the waveforms are also quite ugly, not at all sinusoidal (which is of course to be expected given that the waveforms at the input ports are badly distorted).

I don't know exactly why I am seeing this distortion at the input ports... Is it normal behavior for a mixer? If I understand correctly how a mixer is suposed to behave, the baluns just transfer the impedance of whatever comes after it, in this case the resistive load at the IF port, so

my signal generators should be seeing a 50 Ohm load. Yet the distortion in the waveforms seem to indicate that there is something else going on, like reflections on an impedance barrier or something like it. I just can't figure out what.

I've also seen that people use attenuation pads at the mixer ports (to absorb reflections, I imagine). Would this improve the situation here?

I'd really appreciate any information about this topic. Thanks in advance!

This is a quick guess, but you are driving the mixer diodes with a sine wave with just barely enough to turn them on. So, yes, the impedance is shifting as the diodes are marginally turning on and off.

Generally, I prefer to use a hard square wave on the LO input to the mixer, since this reduces the interval where the diodes are transiting between off and on. The transit time is when the diode junctions are most prone to intermod.....

Anyway, the main point is, you are driving a dynamic load, and so it does distort the waveform, particularly the LO input.

Strongly recommend that you get a service manual for that beastie before tearing into it. I've worked on Wavetek gear, and it can be quite the nightmare without a book.

http://www.manualsplus.com should be able to help.

Good luck.

Ceramic capacitors (especially ceramic disc) are often microphonic.

Hi,

I'm just having to make up the last coil for my grid dip oscillator (the plug-in coils that do the 'sniffing') Problem is, the previous ones were all air-cored whereas this one has to have a ferrite core. With the air-cored ones, I just routed the return connection from the outer end of the coil back through the middle of the hollow coil former. When there's a solid core, I can't do this. Is it okay to just route the return wire straight down the outer edge of the windings? It would be in physical but not electrical contact with them all. I'm not concerned about any minor change in inductance value by doing this, but is that all it should amount to? Or am I going to screw something up this way?

William,

There really isn't any other way to do it, and the effect on the final inductance, especially with a ferrite core, will be negligable. You might want to protect the wire by coating the final coil with epoxy, or by fitting it into a plastic tube. (Pharmacy bottles sometimes work well.) Oops, I guess it would be "chemist bottles" over there.

One other possibility would be to place a piece of insulating sleeving against the ferrite slug before winding, and thread the wire through it after winding, but that sounds like more trouble than it's worth.

Professional coils are often designed so that the final turn
winds up where the first turn started. Small changes in wire
size or coil width are often all it takes to do this. But your
way will not hurt anything. - RM

1319. Re: Doppler Radio Direction Finder - Ramsey DDF1 kit

My favorite null detector with ONE DEGREE repeatable accuracy is from a design pioneered by the Happy Flyers, a group of ham-pilots. It uses a EXAR 211 FSK chip to detect signals picked up by two 1/4-wave whips switched by a 50-50 multivibrator, compared in the Exar chip and feeding two sets of signals out. One set to red/green LEDs to tell one which way to swing the two-antenna array to get to the null "slot" and the other to either a 100-0-100 uA meter for 10-0-10 degree null capture or a 50-0-50 uA meter for finer work. I've built three and used them with helpers to track down jammers and foulmouths. Board/manual sets used to be available from Hart Postlethwaite, WB6CQW, International Commander of the Happy Flyers from his QTH in San Carlos, California.

Anecdote in literature concerned a CAP major flying right seat in a Cessna 182 taking off from Red Bluff, California and flying north to Mt. Ashland in Oregon, tracking an ELT using two pieces of copper tape stuck to windshield of plane. Pilot wearing blue goggles and windshield having yellow mylar attached to it so pilot can have no view of outside world and thus fly on instruments 5,000 feet AGL, using zero-center microammeter as homing device. After flight ended, major stated he watched as plane flew over grove of trees with only vehicle in sight about 300 feet off to side of flight path as meter pointer swung from side to side. Driver of van said he thought it impossible for dead stick pilot to be able to miss the only tree/s in landing so he had put ELT in that grove of trees over which the plane flew.

Prob'ly not, but if you're worried about it why don't you bring the
ends of the winding out at 90ï¿½ from the axis of the coil and detect
sideways?^)

Or, wind two layers arranged so that both leads exit from the same end
of the coil(s)

Can I offer my favourite way of protecting such windings when you are done.
Take a roll of white plumbers Teflon tape. Unroll about 10cms and twiddle it
between your fingers to make a twisted thread. Put one turn of the twist
around the lower end of the coil and then wind on as many flat turns, with
some stretch on, as makes sense for your particular coil. Finish the coil
protection by twiddling a similar length at the finish and tying the threads
together with a double knot. A careful touch with the barrel of the
soldering iron should do a partial melt to lock the knot. There are few
dielectric effects with Teflon to cause errors. This kind of tape is one of
those fixit-all solutions for the home and workshop. Keep some handy.
Luck.

1325. T/R switching for a 100W 2mtr amp

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-22 04:52:50 UTC
From: kc0atc@qsl.net
Message-ID: <a444e1b1.0302212052.442c2f34@posting.google.com>
Source record: 37627

I would like to employ the power amplifier section from an
Aerotron mobile unit as a 2mtr amp. Looking at the
components, it looks like it should be good for 75-100 watts
output with a drive of about 100mw. I will be using
a small handheld to drive it.

My question: can someone give me some information about
T/R switching for this thing? I'm thinking I can do
some kind of detection circuit like in this 40 mtr
amp:
http://www.fix.net/~jparker/norcal/miniboots/miniboot.htm

and then run a relay... is that the right way to go?
Do I need to switch both the input and the output
sides of the power amp? and if I do, then it seems like
I'll need a relay that can handle 100W of RF. Is that
an unusual item or will a pedestrian 12 volt relay do that?

I looked into using PIN diodes, but I don't know how to go
about it.

thanks for any advice...

Thanks for the answer, Jim. Yes, I understand what you mean, the signals applied have to turn the diodes on first to "discover" the 50 ohm load placed after the mixer. It makes sense that they get distorted, and I suppose there is no way around it.

I have tried your suggestion of increasing the LO drive power to (and slightly above) the design level of the mixer, and although it didn't make a big difference it improved things a little. I wasn't very far below before (something like +5dBm instead of +7), and minicircuits specifies that just a slightly worse conversion efficiency is to be expected if one uses lower LO powers (within reasonable limits, of course, which I guess it means just what you said, enough voltage to turn the diodes on).

One thing I wonder about, though, is the effect of using a square wave for the LO instead of a sine. I see why it would be cleaner to open the diodes this way, but thinking of it mathematically, wouldn't this also produce more unwanted components at the IF port as a side effect? After all a square wave can be described as a Fourier superposition of a number of components, and that means that when you send a 10 MHz square wave, together with your 10 MHz base frequency, you are sending also a bunch of -much weaker- harmonics at 20, 30, 40... MHz into the LO port.

Minicircuits application notes -and your own experience- clearly indicate that a square wave CAN be used to drive the LO, and that one can even get better results (less noise) than with a sine, so I am obviously wrong here, but I don't know why... Perhaps the reason is that for this to

have an adverse effect one would have to assume that a mixer is a perfect mathematical multiplier, which it is not... it just uses nonlinear components to produce an effect similar to a multiplication, and these nonlinear components (diodes) have a closer-to-ideal behavior when they are turned on by square waves that minimize transit times. This is just my speculation, anyway.

Message-ID: <b38anh$b9$1@slb6.atl.mindspring.net>
Source record: 37636

Actually, as regards a square wave LO compared to a sine wave in a diode mixer, there are a couple of things to keep in mind....

Due to the required switching action in the diodes, assuming enough drive to definifively turn the diodes on, the diodes themselves will act as a harmonic generator for the LO signal.

So, the mixer will have a lot of harmonic energy from the LO in any case. True, a sine wave LO will result in slightly lower amounts of harmonics, but they WILL be there.

A square wave LO drive results in somewhat higher harmonic energy, but it reduces the interval of time where the diodes are marginally ON/OFF and this will give slightly better protection against intermod products of various signals coming in from the RF port.

Also, by causing the diodes to be hard on or off more of the time, there is a littl more energy getting to the IF port and hence slightly less total insertion loss.

For a reciever, a square wave LO drive tends to be the better choice. Generally speaking, the RF port is low pass protected from seeing any signals at harmonics of the LO frequency so the slightly higher levels generated by a square wave LO drive don't have anything to mix with.

I have successfully modified my Ten Tec Century 21 transceiver, which has a power input meter but no s-meter, to allow the power meter to double as an s-meter.

Switching is automatic through diodes. A slight adjustment of the power calibration pot is required. Works great!

If you want schematics, pics, details, e-mail me.

You might also try www.smallwonderlabs.com for stuff a little more moderately priced.

I love my K1 to death, however <g>. The ATU is pretty nice, but whether it's a "must have" really depends on your operating plans and antenna situation.

The choice of bands also depends on your particular operating interests. 20/40 seems to be the most popular choice, 40 meters is the place where the winter foxhunts live, and 20 is where they hold the summer foxhunts.

If you really hate contests, maybe 30 should be one of your choices. If you operate mostly in the daytime perhaps something like 20/15 would be a better choice.

If you are new to QRP, and want to meet with other QRPers, then 20/40 (14.060/7.040) is a good choice. However, 40 is not a terrifically QRP friendly band except in the dead of winter. Still, it can be a lot of fun. 30 is probably better if you prefer ragchews, less noise and QRM. Keep in mind that 20 closes in the mid evening during the winter in the northern climates, and as the spots decline over the next few years it will get earlier. (I sort of assume that wd1v means you are likely in New England).

Really depends so much on what you want to do...

Sorry, looks like I got my email addresses confused, .it doesn't sound like New England <g>, but still, pretty far north compared to most of the U.S. *BUT*, you now have the European 40 meter band to contend with.

I haven't heard reports from European hams about the K1, but it has a 602 first mixer, which bodes ill for 40 meter operation in Europe. It's got the best implementation of a 602 I've seen, but perhaps you may think twice about 40.

From: markaren10@yahoo.com
Message-ID: <a430c59.0302221939.63397393@posting.google.com>
Source record: 37645

Chris, a few random thoughts:

Keep an eye on harmonics and sproggies from the HT. An unwanted signal at -50dB carrier is much less of a problem from an HT than from a 100W PA - if you see what I mean. I can explain further if you want.

Being somewhat conservative when it comes to RF over a few tens of watts, I personally would go for a Relay over PIN diodes every time. A reasoanable Coax relay for the PA side of things, a small short contact relay on the HT side.

100W / 50 ohms is at least 70V RMS and about 1.4 Amps RMS to put things in perspective.

TX sequencing - I hate the idea of trying to switch 100W of RF (arcs, RFI, destroyed PA etc.). Should be pretty simple to sequence HT/PA/Relay so that Relay has moved to TX position before PA has engaged -- and PA has been disengaged before relay drops back to RX.

Regards, Mark. G8JVX, KE6LVK, G6ANI/T etc. etc.

---

kc0atc@qsl.net (Chris) wrote

I would like to employ the power amplifier section from an Aerotron mobile unit as a 2mtr amp. Looking at the components, it looks like it should be good for 75-100 watts output with a drive of about 100mw. I will be using a small handheld to drive it.

My question: can someone give me some information about T/R switching for this thing? I'm thinking I can do some kind of detection circuit like in this 40 mtr
amp:

http://www.fix.net/~jparker/norcal/miniboots/miniboot.htm

and then run a relay... is that the right way to go? Do I need to switch both the input and the output sides of the power amp? and if I do, then it seems like I'll need a relay that can handle 100W of RF. Is that an unusual item or will a pedestrian 12 volt relay do that?

I looked into using PIN diodes, but I don't know how to go about it.

thanks for any advice... Chris kc0atc, amp.at.yipyap.dot.com

SHRINK TUBE !!! Well durn me, some busybody has gorn and invented a better way. I don't rightly know that this 'ere shrink tube will catch on in this part of the world. We like our string and baling wire solutions for most situations. Particularly helpful back in '43 when knicker elastic just couldn't be had no matter how many eggs you offered. Unfortunately string went in short supply right after the elastic and me dear old duck just stamped her foot over the baling wire solution. Stamped a bit too hard actually and that was the last of the hold-me-ups for the duration and a bit beyond. In the end she didn't really mind - "less laundry" she said. I digress. Can you twist a few threads of this 'ere Shrink stuff to make gland packing string for taps and pumps etc? I guess I am going to have to try this stuff.

Motorola RF Data Manuals give Ap Notes and Engineering Bulletins on building a 300 watt 2-30 MHz module then connecting four for 1KW+. Parts lists, schematics, PC board patterns and parts layouts as well as transformer construction for interstage matching and power combining of the four modules.

Personally, I'd rather construct a Class E amp which can give 92% efficiency with 5% parts and up to 98% with 1% resistors and NPO caps. Now if I could just relocate the construction artivcle. I was browsing through Intel's in-house library one day and came across a "sidebar" article by the fellow who had applied for the patent on that class of amplification. I photocopied the article, took it home and built up a 40-watt amp to use when camping with Heath SSB Rig. It worked GREAT. Lost the rigs and all my papers in move from San Jose to Sparks, Nevada. Keep thinking one day I'll come across the article again. Unfortunately it's not in the archives of Electronics or Electronic Design. Too old an issue I guess.

MRF159 Gemini is good for 10 MHz - 150 MHz according to Motorola RF Data Manual Vol. 2 although construction article in May, '93 issue of 73 Amateur Radio Today claims 12W in/200W out; 7 MHz to 225 MHz, all mode; no tuning [PCB set available from F.A.R. for 7.95 - probably more now] all fits in box 1" x 1" x 1" exclusive of COR.

Hi,
I'm looking for a simple and cheap AM radio IC that will handle
tuning and demodulation. Basically, I'd just like to connect it to an
antenna in and an audio out and do tuning digitallly via another
input. I don't care much about sound quality. Does anyone have any
suggestions for an IC I could use?

Thanks,
Aaron Staple

> >http://www.elecraft.com
> I would be interested in K1-2
> Which two bands do you suggest to start?
> The ATU is a must-have?
==========
Bands : probably 40 or 80 m and 20 m
ATU : Depends of which type of antenna you intend using
If you can accommodate a 'universal dipole' which is a half wavelength on 80m it can be made working on all HF bands.
It has a balanced feeder being 300 or 450 ohms ribbon or an open wire feeder being 2 wires separated by insulating spacers.
Such a system needs a balanced matching unit (tuner if you wish) which can be readily built from junk box /flea market components.

If you will be using an antenna with coaxial feeder ,most built-in tuners will be fine for that.

So before considering a matching unit (ATU) decide on the type of HF antenna you intend using. That decision will largely depend on the available space and local government regulations.

The Elecraft K-2 seems a fine trx and I wish you much success with its construction.

You've made a small error, It wasn't me that made the inquiry but G0ZEN. I'm the one that suggested the BLF 278. Nate Cohen had the patent on the class E amp, but I believe it has run it's course. It was patented already back in 1969. It's not the accuracy of the parts used but rather the values that effect class "E" operation.

W4ZCB
I didn't write the below either except for the response..

As regards strong signal performance, check the Elecraft site for performance data. If memory serves, it is one of the better rigs on the market for that feature and if you live in an area with a lot of RF running around you may need the strong signal handling capability.

thanks guys

it looks like its between the blf278 x2
or the mrf 151g x2..

all i need now is advice on weather to use lumped wilkinson or make it out
of 75r ptfe mini coax..
really needes to have + - 10% of centre frequency without needing tuning or
getting lossy...
coax method wilkinson looks easier and has more bandwidth...
simon

any thoughts on blf279 vs mrf 151g

Try the VHF/UHF DX Book by G3SEK. A pair of 4CX250s
isn't exactly a pair of MOSFETs, but would probably be
a lot easier to get right...

Gotta keep the rigs straight. The K2 is tough to beat on almost any spec.
It's IM is right up there with the $5K rigs. But the K1 is a lower priced,
lower performance rig. Still a dandy rig, but probably not what you would
want to be using on 40 from the middle of Europe.

Recently I have been trying to use 1/2" CATV hardline to feed my vertical antenna. The cable is a little larger diameter as LMR-400 or any other .405 OD coax. It has a solid center conductor with foam dialectric that is glued to the center conductor. The jacket is aluminum, and there is no PVC outer jacket. The connector was crafted from a PL-259 and a brass double female 1/2" compression fitting. That experience has taught me a couple of things, and raised some questions. If anyone has any helpful comments about the following, I would really appreciate hearing them.

I discovered very quickly how a kink in the cable is a disaster. Thirty feet from the end of a 200 foot run, the cable kinked and the outer metal jacket ruptured. Bleah. How disappointing.
Can anyone tell me good, cheap and durable ways to splice the cable?

Talking to a friend, I mentioned that I didn't plan to bury the cable but for a short run to make sure it isn't run over with the tractor. He asked me, "Wouldn't that change the impedance?" I had to admit that I don't know, but didn't think it would since the jacket is ground anyway.
I could not find the answer to this question anywhere. Can anyone tell me whether buried / not buried will change the impedance of this feed line? Are there advantages to burying the entire run? Are there any wild aluminum eating creatures that nibble holes in hardline?

Finally, does anyone care to share any hard-won experience, or pointers to complete information, or whatever?

Thanks in advance for any help,

73,

Adam Adkins, KM5N

I have a Kenwood DM-81 and I think it's one of the best made and very
convenient to use. It has a socket for testing xtals and a probe to couple
to difficult items. All the coils are in clear shrinnk tubing with the cloi
number and freq. range on a piece of paper. It's a great idea.

Can't help you there. I've only `slightly` kinked either the 1/2"
or the 3/4" stuff but once each -- and it did not burst and I'm
gonna live with it.

Mox nix -- being ground. What you'll get is a smashed tube - with
the outer wall much closer to the inner conductor - giving you
(perhaps many - depending on how active the tractor) impedance `bumps`.

[Oh, now that I've re-read the question: No, burying the hardline
directly, or in-directly will *not* alter the impedance. sri]

Without _any_ poly jacket, you need to worry about electrolysis and/or
the PH of the soil. If it were me: I'd bury it in some black poly pipe.
'Twould be a feat to stuff in a looooooong run of it...

> Finally, does anyone care to share any hard-won experience, or

The TS830 has a partially synthesized hfo chain and a frequency counter
display.
Rigs that are totally systhesized (pll/dds) show the desired air
frequency while rigs
of the TS830 generation count the result (which changes based on the
carrier osc and
cw offset). It's not that it's less confusing not to show the offset in
the new rigs, it's
that they generate the offset AFTER the air frequency is selected, while
the TS830
HAS to show the result.

You will never find a tech that is worth anything using a splice made from foil and clamps. There are splices manufactured specifically for this purpose. You might try approaching your local cable company to see if you could buy one, but you will also need a coring tool and prep tool to properly install it.

Was not talking about a whole cut, dress, core & splice. There's some kind of patch kit used by service techs to patch a cracked shield until a splice was installed (or the whole span was replaced). Was a fix for CLI. Some of these temporary fixes are still up after several years keeping the shield intact.

I don't stock them anymore, but bet I could find some in a few tech vans.

Simon,

SD1407 is only spec'ed to 30MHz at 15dB gain.

However, I believe that you take a 4dB per octave hit on gain, so if
you ran it at 90MHz :) you might still get around 7dB gain.

Mark.

Hello all,
I just picked up a Icom IC-R2 handheld scanner, 25-1300Mhz discone (http://users.cis.net/kingpop/Superdiscone.htm), 40 feet of Belden 9913 cable and 30 feet of mast(radioshack)to start listening to the world.

I would like to build my own preamp with several sets of filters (10-20)to knock out the high power RF (radio,pagers, ect.) I am thinking of using a minicircuits ERA-3 monolithic amplifier (http://www.minicircuits.com/dg03-168.pdf) but if someone knows of a better amp, I'll use it.

My main questions are this:

What frequency bands should I target with the filter sets?
The FCC alocation chart I have shows what is licensed to each band, but does not mention alotted power.

What software would help me quickly find the component values for the filters?
The simpler the better!

Would I gain anything from cascading ERA-3s? Could I set them up for variable gain? or would I have to switch in attenuators to prevent front end overload?

What type of remote filter switching scheme should I use? I want to be able to control the preamp from inside the house. I know that relays tend to be noisy, so those are out. Transitters?

Im sure an RF guru could help me out here.

Thanks for reading,

Jason

1375. Re: AM radio IC

Also, the Phillips TDA1072 or the TDA1572 will do the trick. You will need external components for the oscillator, ceramic filters, etc. This is a high performance AM radio on a chip. The 1572 is used in both the Linn Kudos tuner
(LW/MW section), and in the AOR7030 as the 2nd I.F. subsystem. It is a relatively easy chip to implement, although not as simple as the two aforementioned examples.

That is a huge frequency range and no antenna is going to work well on that entire frequency range. It might be a good idea to split the frequency range into at least two bands, say 25-250 and 130-1300 MHz and use two separate antennas designed for those ranges.

> I would like to build my own preamp with several sets of filters
>(10-20)to knock out the high power RF (radio,pagers, ect.) I am

>better amp, I'll use it.

Those MMICs are cheap, why don't you build a complete preamplifier for each band. Filter switching is nasty at higher frequencies, especially when it must be remotely controlled. You could feed the outputs from the various preamplifiers through some combining filters to a single feed line and only switch the DC supply to the various preamplifiers.

When using multiple amplifiers is the tower, there is not much to gain from a single ultra-wide band antenna. Use multiple antennas designed for each frequency range of interest. Usually there is not much point of using preamplifiers below about 200 MHz, since the band noise is quite high and the cable losses are low.

Stripline filters are nice for the upper UHF frequencies, while at VHF, ordinary coils and capacitors or helical filters (e.g. Toko) are nice.

Those MMICs can be easily overloaded, so make sure that the strong signals from nearby FM or TV transmitters are filtered out prior to running the signal through the ERA amplifier.

>Would I gain anything from cascading ERA-3s? Could I set them up for
>variable gain? or would I have to switch in attenuators to prevent
>front end overload?

The antenna amplifier should only compensate for the feed line loss and mask the receiver noise, so a good rule of thumb is that 10 dB should be added to the cable loss to get the required preamplifier gain. Handheld scanners are very easily overloaded, so there is not much point of using too much gain, even if the input is filtered.

1377. Improving the dip of a GDO

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-24 09:56:50 UTC
From: Paul Burridge <redscar@waitrose.notthisbit.com>
Message-ID: <r5qj5voi5irhu8eg0c9qcbtudat0h6567v@4ax.com>
Source record: 37579

Hi,

All the GDOs I've seen seem to incorporate a different resistor into each plug-in coil so that when you change coils, you also change the resistance value associated with that coil. I've found it a worthwhile improvement to do away with these resistors and simply connect their socket connections to an externally adjustable variable resistor whose value is next preferred up from the highest value coil resistor. When in use, one simply adjusts this resistance for minimum stable oscillation - just above the point where the waveform collapses altogether. You will then get a *much* better dip. The incorporated fixed resistors aren't ideal for the task and cause a lack of sensitivity and often barely perceptible dips. This method results in a vast improvement and generally a full-scale dip.

The question is : Do you really need a pre-amplifier ?
Not knowing the frequencies of the high power interfering radio sigs and
whether there are other nearby frequencies you would like to monitor , I
would suggest to initially consider a simple (multiple) quarter wave stub
arrangement , to suppress the most troublesome RF sources.....and
take it from there.

==========
Suggest you use flexible 'alkathene' (polyethylene) water pipe
In Europe (incl Britain) it is available in 20 , 32 mm diameter and larger
sizes
;colour is blue.
I use this pipe also for coax cable with copper braid and black sheathing ,
ie for underground 75 Ohms coax to a TV satellite dish as well as for RG
316 ,50 Ohms coax to a vertical HF antenna.
It is important that the pipe at the outdoors end is properly sealed to
prevent
water running into it.
Alternatively (that's what I have done) where pipe with coax come above
ground outdoors there is a half circle bend resulting in the pipe opening
pointing downwards ,hence rain water can not enter and the circular opening
between pipe and coax cable is left open for breathing.
I realise the latter method might not be suitable for hardline coax because
of the bend's radius.

What you are doing is raising the "Q" of the coil. Nothing wrong with this except when you try to dip another high-Q circuit -- you might miss the resonant point.

I can tell you from personal experience (we make thoudsands of them) that targeting, say, the 152-153 pagers and not also eliminating or radically reducing signals within many MHZ either side is far from a trivial problem.
The IP3 levels of the MAR and ERA devices make them unsuitable (IMHO) for preamp use.
In almost every case, wideband preamps create problems far worse than they solve. Put a good quality feedline on your antenna and forget the preamps.

>
> What frequency bands should I target with the filter sets?

You would probably want to block everything below 25 MHz
(scanner is not real HF radio and overloads easily), 87-108 MHz
(FM is very strong and not interesting), 152-153 MHz (unless
you want to decode pagers), 108-116 MHz (AIR beacons)
and maybe 116-136 (unless you want to listen to airplanes).

Start with high-pass 25 MHz filter and FM 87-108 MHz notch.

>
> Would I gain anything from cascading ERA-3s? Could I set them up for

R2 is extremely sensitive. Amplifier will make things much worse
- especially with additional outdoor antenna. Forget the amp and
prepare few attenuators: 6/12/18 dB. You will probably find them
much more usefull.

Good luck!
Piotr

I hate to say this, but hooking a handheld scanner to an outdoor antenna and then addind a preamp is a BAD idea.

Handheld scanners have poor intermod immunity for several reasons. They are designed to minimize current draw (which drains the battery). That precludes the use of high IP3 mixers. They usually do not provide pre-selector filters either due to space constraints. Basically, they are meant to be used as handheld radios with a small rubber duck antenna.

A good desktop scanner like the Radio Shack PRO-2004 series incorporates a series of bandpass filters (about 10 as I recall) in the front end to reject unwanted frequencies. The appropriate filter is selected as the radio scans through each programmed frequency.

Hello,
I just put on the web, my last program for EVM56002 board :
http://thierry.leconte.chez.tiscali.fr/radiodsp01.zip

radiodsp is a program for the EVM56002 motorala evaluation board
that implements classical DSP audio filters to improve ham radio reception.

Its features :
- an AGC
- a band pass filter with 4 selectable bandwidths (100Hz, 200Hz , 1500Hz
and 1800Hz)
- a auto notcher
- a denoiser

For more information see :
http://thierry.leconte.chez.tiscali.fr/radiodsp.html

A K1 is a good choice for your first kit building experience.With sunspots going down, a 40 plus 20 m combination is probably the best. If you construct an OCF/ also called Windom/ dipole, cut for 40, you can use it also on both bands with coax feed, without a tuner. Or cut two dipoles, one for each of the two bands.

If you want to use end fed wires or a dipole with ladder line feed for multiband use, you will need a tuner (and a balun for the cf dipole).

Alternatively, buy the MP1 antenna from Elecraft, which you can adjust for proper matching.

Good luck!

I don't think that's what's happening, although I may well be wrong.
SFAIK, I'm simply loading down the oscillator's output until it's on
the verge of collapse, whereupon, the slightest extra load (in this
case from the tuned circuit under test) will cause it to show a sharp
dip at resonance. It's kind of like raising the GDO's unloaded output
impedance to the maximum possible before each test.

Thanks, Paul, I've got about half a dozen data sheets of varying opinions on the device and as yet (until I can find out how long the pipeline is expected to be open and other "manufacturer" questions) I don't need a working part.

Jim

Paul Burridge <redscar@waitrose.notthisbit.com>

The ERA series are very good. The only thing I would say is that they don't tolerate overdrive well at all. Follow the manufacturer's data sheet and stay well below the maximum drive to avoid "popping" these devices...

Jason,
I have two radio shack scanners, an RS-2045 (a base) and RS-64 (a handheld).
The 2045 gets a lot more use at home because it allows attenuation to be individually selected for each channel. Adding a preamp will probably just overload your scanner, especially if you live anywhere but out in the country.
But a cheap test might be to put a TV preamp inline with your discone. The discone doesn't have gain to speak of, and you will lose a little of what you receive on your coax, so something like 10 db of gain might not bother you. You will probably want to switch in the FM filter if it has one. Of course using this set up you won't be able to scan all bands, but it will give you a feeling for how much help a preamp can be in your situation.
If you locate something distant you really want to hear, you might investigate a second antenna such as a log periodic, it has gain, bandwidth and is directional.

Good luck, Jim

Pick up a Measurements #59 (or the newere 159). These meters make the
Heath, Millen etc look like toys. You can get a huge dip on 1 meter rod by
simply loosely coupling to the center- try that with the others.

The Small Wonder kits are excellent kits. I've built the SW20+ and SW40+. However, they are not on the same par as the K1. They are a bit more simple, which I'd suggest as a starter QRP kit. I will also say that they are easy to build & align once built. They perform quite well but lack some of the bells & whistles found on the K1 & K2. But, as I said, the simpler design might be a better way to get started in QRP.

This is exactly what Ale needs, someone from Europe who needs to put up with the conditions there! And I think you are saying that you've had a reasonable experience on 40 with the K1? I, too, like the 40/20 combination, but I don't have to put up with the interference on 40 that you do! I assumed that a 602 wasn't the ticket in Europe on 40, but the K1 is a very good implementation, so hardly typical.

I'm surprised these things are readily available. The 414 is at least
thirty years old, and while it is a neat little IC, I can't help but
think there was never much commercial application. You rarely come across
a commercially made TRF radio. So either we are just seeing the slow
sell-off of an over-optimistic first run of the IC, or there is some
odd use for them. And since there were two followups, it's an even
greater puzzle.

This site, from a websearch, http://www.thebest.net/wuggy/comments.htm
says that a place named "Kitsrus" says the MK484 is out of production,
but there are 500,000 in the pipeline. It mentions also that the other
two are out of production, too. But not a word about the mythical
manufacturer.

I bought one of those $1.99 FM radios, the kind with a scan and a
reset button, when they dropped to two dollars. I was simply curious
about what was inside. I thought it might be the Phillips TDA7000,
which also gets lost of mention in hobby circuits but I could never
figure out the commercial market. It wasn't a match. But Phillips
had some for this type of radio (the circuitry for the tuning
included) and the circuitry I traced matched another Phillips IC,
I think it was the TDA7088. But this IC looked like either a knockoff,
or second source from a company that is cutting costs.

So whoever makes the MK484, I suspect it is some obscure cut-rate
company that is selling to radio manufacturers who want the absolute
lowest cost.

If I saw $1.99 AM radios, I'd immediately buy one, with the suspicion
that it had an MK484 or something similar in it.

Hi Piotr,

I am planning to do exactly the same like you describe above, i.e.
build a High pass filter that filters out anything < 30 MHz and
and in series with that a band reject filter 88-108 MHz (in future
depending on the need maybe even some more filters).

Do you have any experience with this?
I mean: Is it possible to cascade the filters just like that?
At least they should have a 'load' of 50 Ohms at the input and
output. If I would have one filter, it's no problem:
Antenna is 50 Ohm (input) and receiver is 50 Ohms (output).

But what if I want to cascade the filters? I reckon that I need
to put a 50 Ohms resitir in series with the separate filters...
Do you have any plans or schematics?

Cheers,
/Marc

Hi Marc,

I built high-pass 25 MHz filter because I had problems
with MVT9000 in low-VHF band (intermodulation).

After adding this filter between outdoor discone and
the scanner, the problems were gone.

You can find my design on:
http://www.geocities.com/bpiotrek/hpf25_e.html

I haven't try FM notch yet because I want to try building
my own circuit before spending money at store (building
circuits is a part of the hobby for me).

As for cascading the filters: it is possible but the resulting
characteristics will be a bit different than simple superposition
of the characteristics of both filters. I don't know how much
it could affect receiving.

I think it is very good idea to separate both filters with small
attenuator. The primary purpose of the device here is not
attenuating the signal but 'terminating' both filters so they can
work 'normally' (similar approach is very often used, for example,
in antenna amplifiers to suppress the results of variable load
impedance). Simple 3...6 dB attenuator in 'pi' or 'T' configuration
should do the job (50 ohm resistor put in series is not a good
solution because both filters should 'see' 50 ohms and not 50+50).

Cheers,
Piotr

You can always cheat and use a RF modulator that works on
cable channels 59-60 and add an amp and low-pass filter. Don't
know how good that would work without trying it. I tried a variation
on that theme and it worked OK: a wireless VCR Rabbit (900 MHz
band) with a 12 watt amp.

Commercial ATV transmitters do more than you think. Most mess
with the sync pulse to give a better final signal (after being
amplified). Handling audio takes some work, too.

If you are really interested look around for ATV Quarterly magazine.
It always had decent construction projects and they used to have
an email reflector. Don't know their current status, it's been a
while.

I build mine as a bridge circuit with uA meter across the middle. It is bit of a pain to keep the needle roughly mid-scale throughout the coil frequency range as the oscillator current changes, but it offers good sensitivity if the pot and oscillator supply resistors are fairly small, and the meter movement sensitive.

You can view my version of Pete's RX at:
http://www.parelectronics.com/pics/old/Pg150.jpg

I am very satisfied with its performance. Still working w/ different AM sync detectors and ceramic resonators to fix the USB and LSB BFO injection frequencies.
Also added a Collins 2nd IF filter for better CW/SSB selectivity. Pete's major aim was an AM RX- and in that regard the Philipps 2nd IF/ full wave AM demod yields the best sounding AM of ANY RX I have owned- and that's a pile of 'em.

Paul,
AFAIK this is an add-on to measurement receivers and will do a
spectrum dsiplay. Not sure of the data but think it will act as a 1
MHz spectrum analyzer.

It does have MS-Dos but I have no special?? keyboard to go. It will
accept a floppy-drive but it is apparently an option not intsalled.

Tain't all that bad. Just use a large enough pipe and don't forget to
get some "wire soap" which is available at most electrical supply
stores. The ugly looking yellow soap makes the cable slippery and
allows pulling far more through a pipe or conduit that seems possible.
You just slop the stuff on, don't use sparingly.
I had two 350 foot runs plus a smaller quasi air core cable and two
runs of 9913.

Then again, at one location where we had dry sandy soil I just buried
the stuff with no extra protection.

>================
>Suggest you use flexible 'alkathene' (polyethylene) water pipe
>In Europe (incl Britain) it is available in 20 , 32 mm diameter and larger
>sizes
>;colour is blue.

My favorite is either the larger sizes of plastic conduit (1/4 inch
wall for mechanical protection and sweep "L"s for corners.

I've also used 5 inch plastic sewer pipe with good results.

>I use this pipe also for coax cable with copper braid and black sheathing ,
>ie for underground 75 Ohms coax to a TV satellite dish as well as for RG

For my two C-band dishes I just bury the cable direct.

>316 ,50 Ohms coax to a vertical HF antenna.
>It is important that the pipe at the outdoors end is properly sealed to
>prevent
>water running into it.

Water was/is the least of my worries. I use a water trap/drain just
before the pipe goes through the basement wall.
The trap is a 45 degree fitting with a cap over the bottom. The cap
has a bunch of 1/8th inch holes drilled in it to allow the water to
drain. The 45 is on the bottom of the pipe and in the sandy backfill
for the basement.

>Alternatively (that's what I have done) where pipe with coax come above
>ground outdoors there is a half circle bend resulting in the pipe opening
>pointing downwards ,hence rain water can not enter and the circular opening
>between pipe and coax cable is left open for breathing.
You don't have problems with varmints, bees and bugs, do you? <:-))
I removed 14 Yellow Jacket nests from the one satellite dish alone
last summer. The things got into the vent for the kitchen range, under
the sewer pipe vent flange, in electrical boxes, In the eaves, in to
soffit, and under the siding near the peak of the roof on the south
end. That particular nest was so large it pulled the siding away from
the house and had to be renailed. I used 14 cans of Wasp and Hornet
killer. As I recall I removed over 40 nests...only got stung4 times.
Three by Yellow Jackest and one by a wasp.

I had a TV tower stacked in the back yard. They built nests in the
legs. The things even built nests in the vertical mast at the top of
my tower, making it more than a little difficult and hazardous to work
on the antennas.

I use a " 20 X 20 Hoffman box" at the end of the pipe.
http://www.rogerhalstead.com/cablebox.htm
The conduit fitting is mounted right on the bottom of the box. All
outside openings are *sealed* with the expanding insulating foam.

NOTE, I am no longer using the 3/4 inch hard line.

Cables come down the tower, form a loop and then enter the box through
a 8 inch long conduit stub. The Yellow Jackets went up the cables and
built a nest in the box., but due to the seal they couldn't get into
the house. Prior to sealing I even had mice crawl up the cables into
the box and then follow the 75 foot run of conduit into the house.

>I realise the latter method might not be suitable for hardline coax because
>of the bend's radius.

Use a Sweep L, or in the case of the flexible plastic pipe, just bend
the whole works over about a 1.5 foot radius. (half meter radius)
If the plastic pipe/tube is a relatively close fit it will help
prevent the aluminum jacket from collapsing. OTOH not much can be
done about the thin jacket on half inch hard line except a wide radius
bend and being very careful..

I'd still seal the outside end, but leave the inside end open. The
thing only needs one end open for breathing and I prefer it not breath
in high humidity and critters.

BTW, the Tower project and station are shown at
http://www.rogerhalstead.com/tower.htm . NOTE, this is a large page
with lots of photos and runs on the order of 2 to 3 megs so unless you
have a fast connection it will take forever to load.

Philips TEA6200 seems to be a very interesting device, unless you wish
the advices you already knew, see
http://www-us9.semiconductors.com/acrobat/datasheets/TEA6200_CNV_2.pdf
It is a quite unusual device, makes it possible to use high IF and
cover the two AM bands (LW/MW) 150-1600kHz with ease, this is mainly
because it has a high IP3 mixer

I've been looking into different applications where this device may be
an advantage

But I still miss synchronous AM-detector or simplified version of it
which might be a vaste improvement, then Philips TDA1576 or NE/SA604
would be possible choices. I've already put some possible demodulators
on my site, perhaps MC1351P and MC1357P still have some interest?

From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <3E5C08A5.C48CA67E@alma.demon.co.uk>
Source record: 37525

The last two posters win a prize ;-).

It may have been the coil/cap combo. I bought a box full of pre-wound coils on formers which had come out of some radio equipment. By chance one type of coil/cap resonated at around 50MHz, so was perfect for my 6m rx. The cap is a small 22pF ceramic.

I did tap all components but it still wasn't 100% clear which was to blame. A poor inoccent 22k ohm resistor was the first to be removed. I finally replaced the coil/cap combo and the problem appears to have gone away. There's still plenty of other problems with the rx though!

thanks for your suggestions...

Hello all,

I have this receiver:

http://www.ott.igs.net/~jcb/misc/csr2/csr2.html

I hoping that some one has general historical / service / operators info on it. I have it working well, and before I start searching to see whether it would be appropriate for a local museum, I'd like to know a bit more about it.

To those who will email asking :: no, it's not for sale.

thank you and cheers

It is very nice of you to offer me help, I might have to use it. I got the
code
for the DDS as ASM and HEX. As a start I was just asking to find out if
it was somthing to build, and I now am convinced and I will start looking
a little deeper into the schematics. My plan was to build it as a black
box with only the display on it and do all the control from my computer,
something like a Winradio, but homebuild to a mich lower price. I already
have several Ham and SWL radios, but I would like to have one by my
computer, my radios is down in the shack in the cellar and my computer
is here in my office on the first floor, so it would be nice to have a radio
here to monitor the bands. I will mail you when I am a little more wiser,
I am shure that there will pop some questions up on the way.

Source record: 37539

I would like to add an extension to an HF radio in the shack. The speaker is amplified thus requiring 12v DC. The length of wire
required will be approx. 15-20'.

Should I be concerned about using a 'special' (e.g. shielded) wire for audio?

Any recommendations for wire? Seems to me over the years I've read of guys using a certain coax for speaker wire ... but the memory
is not clear.

Thanks for the help!

I have the R & S ESH 2 receiver.

I imagine what you have is a matching Panoramic Display Unit with a
10.4MHz IF in. I could be wrong.

I could also be interested should you decide to sell. It would make a
nice companion to the rx, especially if it works.

1439. SAW osc ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-26 23:08:06 UTC
From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <v5qi6qcbc4fh47@corp.supernews.com>
Source record: 37542

My HP 8950a spectrum analyzer is deaf and this could be becasue the 3rd LO/Cal. Out isn't operating. It has a surface acouttic wave (SAW) oscillator running at 299.9 MHz. The oscillator time by Y1 which is a SAW device, two transistors and associated components. The module is intermittent, however it's on a pcb that needs an extender that I don't have and poweron testing is nearly impossible. On rare occasions I can see 299.8 MHz on my counter especially if I turn the L1 slug,and then it can jum to 313MHz or higher but most of the time nothing. On low band I sometimes count 40 to 50 to 60 odd MHz. As you can see I don't know doodly sqat about SAW devices and would like to know how to test these things. Hopefully something else is bad because I understand it's unobtainium. All help appreciated.
tnx

I couldn't get anything but 404 from your earlier posted web page,
but this one works. Thanks for sharing the information - especially
the "DIP"-meter with the HF-generator. As long as I don't have to
carry my generator onto the aerial tower it's OK. Up there I prefer
a FET-dip-meter :-)

Kind regards, Eike

1445. Powerpoles and Powerwerx

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-27 01:39:33 UTC

Source record: 37398

Guys,

I wish to share my impressions regardind doing bussiness
with Ken Mirabella.

I decided to connectorize my power cords with Powerpoles. I
have a dealer in Sï¿½o Paulo, Brazil that carries the PP45
line. They are charging US$3.6 each pair. Molex type
connectors are about 50 cents. They can send me the
connector the same day.

But, as I am also considering buying a Rigrunner, I checked
Powerwerx for prices.
The price range is good, but there was no way I could send
it to myself... Brazil wasn't on the country list.

An email sent to Ken, and he promptly added my country! The
shipping options didn't allow for (very) small orders, like
mine...Just 25 PP45 pairs. Another email and Ken promptly
added another shipping option!

This guy is awesome!

While I was writing this, Ken wrote me again. There is
nothing I can say to express how he care about his
customers... I haven't even placed the order!!
That is Customer Relation Management!!!

NOTE: I am in no way affiliated with Ken, Powerwerx or any
other company implicitly or explicitly mentioned on the
message.

The led should go across the load (from the switched side of the switch
to the return)
and you do need a resistor in series with the led. Most leds have a
voltage drop across them
from 1.5 to 3 volts and run at 5 to 25ma. So with a 6 volt supply and
assuming a 4.5 volt drop
at 5 ma you need a 900 ohm resistor. Depending on the led, typical
resistor values of 220 to 1k
ohms are used. If the led doesn't get hot or isn't too bright you can
pick something in this
range.

A half watt resistor will be fine.

1451. Has anyone here used a chopper amplifier before?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-27 05:29:37 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0302262129.175ef251@posting.google.com>
Source record: 37404
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,sci.electronics.design,sci.electronics.components,alt.engineering.electrical

Here is the application:
I am working on an SWR/wattmeter with a wide dynamic range. The design is just like the one at http://engphys.mcmaster.ca/~elmer101/rfpower/swrtheory.html except that I will need a more complex rectification system. I use the same 10:1 turns ratios and the same 50-ohm resistances. The sampled forward voltage is 10V at the top power transmitted power level (200W) and .1V at the lowest transmitted power level (20mW). For an SWR of 1.22, the sampled reflected voltage will be 1V for 200W of transmitted power and .01V for 20mW of transmitted power.

The problem:
I am trying to rectify the RF voltages into DC voltages of the same amplitude. The frequency range is 1.6MHz-30MHz, and the voltage amplitude range is .01V to 10V. RF amplifiers are not a viable solution (not equipped to use SOICs, all my supplies are DIP). Amplifying the DC voltages with an ordinary op amp will not work due to the contamination from the offset voltage. And conventional audio op-amps like the 741 lack the bandwidth I need. So the only solution left for me is a chopper amplifier, which converts the DC voltages into audio frequency voltages, which are much easier to work with than DC or RF.

The questions:
What should I look for in a chopper amplifier? Did any chopper amplifiers that you have worked with have strange characteristics that affected performance? Are there any other issues I need to be aware of? Tell me about your experiences, because I have never seen a chopper amplifier before and have absolutely NO experience with any.

SHAMELESS PLUG ALERT!

I'm a Motorola reseller that specializes in service to the amateur
community. If you can give me the exact model number of the repeater,
I'll see what I can find out for you.

It will likely begin with 'C73,' and will have a whole string of
other characters after it. Look on the side or edge of the cabinet for
the model/serial plate, and either post a note here in the group or drop
me an E-mail (your call).

Thanks much.

Well, there are a lot of inexpensive opamps that have bandwidths that
are in the hundreds of MHz (SOIC and DIP) that make RF amplification
easier than you seem to indicate.
And, there are a lot of cheap opamps that have low microvolt offsets.
So, with either of those as a solution, you will be better served,
since it is a bitch to rectify that 10mV signal.

Hi Hank,
I would try injecting a signal from an RF Generator at that
point. Use -30dBm as an initial starting level, and increase it slowly, to
see if there is a response. I probably wouldn't try more than 0dBm,
although if a diode ring mixer is being fed, +7dBm would be an ok level. I
am not sure if you have the service manual, but that would give you the
level chart.

A log amp would do the job I think.

I suggest you check http://analog.com

They have a range of log amps such as AD8307, with a dynamic range of 90dB @ 500MHz. I think they have DIP versions available. The data sheets include applications information for a 1uW to 1KW RF power meter using a single IC.

Sorry - That should be http://www.analog.com

This is a direct link to the AD8307

http://www.analog.com/Analog_Root/productPage/productHome/0%2C2121%2CAD8307%2C00.html

An 8 pin DIP version is available.

I suggest that you take a look at "The Tandem Match - An Accurate Directional Wattmeter", by John Grebenkemper, QST, Jan. 1987, pp. 18-26. Also see "Tandem Match Corrections", Technical Correspondence, Jan. 1988, p. 49.

When I looked through the Analog Devices solutions bulletin of this month, I saw this AD8362 RMS-detector on the last page, which might serve for your purpose. It will require a bit of understanding to modify the chip for an SWR-meter, or even require a second one. The 60dB range and the fantastic bandwidth are promising though.

On the other hand, it wouldn't be that difficult to phase-sensitive detect/demodulate it by multiplying with the transmitter frequency.

You may have to do it twice - in-phase and in quadrature - to reliably capture the amplitude of the detected signal, but since this also gives you phase, this may be more of a feature than a bug.

The Analog Devices AD834 and AD835 parts are the first ones that come to my mind, but more RF-oriented engineers will think MiniCircuits mixers, and Jim Thompson will probably point out that the MC1496 is cheaper and quite fast enough.

Try taking the module out and inspecting it carefully under a
microscope or with a jewler's loupe ... use appropriate static
protection, of course.

The cause of intermittent operation could be a cracked solder
joint, a cracked chip cap or resistor, corrosion, etc. A careful
inspection may yeild the source of a relatively easily fixed problem.

Offset voltage is not a problem; you can simply introduce an identical
voltage of opposing polarity to null it out. The real issue, of course,
is whether it stays nulled out, or if something changes with temperature
or something else so you can't count on it.

I hate to say this, but it sure seems like the reason you are
now asking about choppers is because on the last iteration, you
got some suggestions of using them. But that was crossposted,
like this one, and I'm still not convinced choppers are necessary.
In other words, you may be going down a false path, based on
an initial false premise.

I can't remember ever seeing choppers in hobby circles. Oh,
people fiddled with them forty or fifty years ago, so they could
see DC fluctuation on their AC coupled scopes. And I suppose
there were some highly critical and very obscure use of them.
But the fact that you don't see them in hobby circles seems
like a good indication that you may be looking at the problem
wrong.

The only exception that immediately comes to mind was something
in Ham Radio magazine about 1978, I think by Joe Reisart, where
he used an AM modulated signal source, and then could use an
AC coupled amplifier after the detector. But my memory of
this is vague enought that I can't even remember what exactly
he was doing with it.

I think the initial problem is your misunderstanding of
offset problems. But to dismiss things like RF amplification
for trivial reasons like you can't find them in the right package
(people were building amplifiers long before there were ICs)
and likely plenty of other solutiions, before dismissing
choppers seems like you're going down a false path.

While I was looking for something else, I came across a couple of references that would apply. After a month, and over forty replies, I'm not going back to see if anyone has pointed them out.

The December 1997 issue of QST had an article about crystal radio building, "The Crystal Radio" by Dave Evison. I've never seen it, so I don't know how valuable it might be.

But in the August 1998 issue, there is a letter in the Technical Correspondence column about the article. The writer pretty much dismisses the need for high impedance headphones. The orignal writer then responds, talking about how important it is, and including some bits about how to match the coil to the headphone's impedance.

In the September 1998 issue, there is "The HZX Headphone Adaptor" on page 67. He describes a headphone amplifier using an op-amp, but makes the point that this is more as an impedance adaptor, to make use of readily available headphones, rather than an attempt at getting more sound out of a crystal radio. Before he gets to the circuit, he discusses passive solutions. And throughout the article he has bits about different types of headphones.

I live about a mile (as the crow flies) from the university where I work. The university has a robust wireless system such that I can reach a wireless access point pretty much anywhere on campus... inside and out. From my deck, I can see the campus and if I take my laptop with a wireless card out there, I can occasionally get a "blip" on the cisco signal tracker. My question is this. Couldn't I get a higher gain antenna (or build one), hook it to a wireless PCI card for my desktop and be able to connect? The transmitting power of the card, is 100 mW but with a high gain antenna, shouldn't I be able to get the signal there? I have gone alot further with QRP type stuff but I am pretty nieve at this frequency.

If you have a clear path (which may be the case, since you say
you get an occasional "blip" with just the "normal" antenna on
your laptop), you might well be able to make the link.

I've done the link budget for the path from my home to my
company's nearest building (I telecommute from a home
office) and at over 8 miles, I'd have margin to burn for an
11Mbps link if I used standard 15-18 dBm output cards
with 23 dBi directional antennas at both ends of the link.
(However, I do have to point out that I "hold the high ground"
in that my house is on the highest point in the area with a quite
clear LOS view of the entire valley below in the direction of my
company's facility.)

Just remember that Part 15 equipment is certified for
use as a system with specific antennas and to substitute an
antenna that your PCI card wasn't certified with would be
a violation. (Yes, I know that people occasionally do so,
but it's not legal and you don't want/need the grief that such
a violation could cause.)

Mark, thanks very much for your comments.

I was thinking... _if_ I can ensure that the
input to the amp is off when any output relay switching
occurs, shouldn't I then be able to us a smaller
relay at the power end? If I have to buy a new
coaxial relay, then I'm pretty much sunk.

For example here's some ASCII art:

```
rf 2 o--- AMP ---o 1
HT --{detection}----O---- ----O---- ANTENNA
circuit 3 O--------------O 4
relay 1 relay 2
```

If I can follow the numbers in my switching...
I think the relay at the antenna end would always
be switching while the amp is off. On transmit,
I would do #1 then #2. At end of transmit I would
do #3 then #4. I figured out how to do #3-->#4
using a capacitor in series with the relay coil.
But I haven't figured out how to cause #2 to come
after #1.

So, I was looking at a TR time-delay generator
project as shown in the 2001 ARRL handbook.
It looks to me like I could use something like
that to switch the hot end only after the
input had been switch out.

Does that sound good?

The tantalum bypass caps on the 15 volt busses are problem prone,
and will short. I'd had several module failures because of bypass
tantalums shorting.

The module is held in by the screw you noticed.

Heck, with the cascaded 9 MHz and 455 kHz IF filters, you might
want to think about adding variable BW and/or PassBand tuning.

Good suggestion! Several greater-than-60-db RF power
meters have been made by Danish and German amateurs,
all covering low HF on up to edge of UHF. The most
illustrated website I've seen is by Thomas Scherrer, OZ2CPU.
(couldn't confirm that site just now due to ISP having fits)

Trying to chopper-stabilize amplify the DC out of diode
detectors of anything...and assuming accuracy better than
50% at low levels is not a good choice. It will also beget
more problems than expected since the diode detectors
themselves will drift away from a semblance of calibration
depending on ambient temperature. The AD8307 and other
"log amps" in the Analog Design family are amplifier chains
with successive detection and are also temperature
compensated over AD given specs.

Scherrer's website and power meter project uses only an AD
log amp plus a programmed PIC microcontroller for readout of
the logarithmic-scale DC out of the log amp and also to drive
a 2 x 40 character LCD display to show dbm or Watts
directly...and whatever else is desired on the display panel
(program adjustable). Others building the same power meter
in Europe have customized their displays as desired.

To measure forward and reflected power, a passive transformer
arranged as a directional coupler can be used...and can be
calibrated, both as to coupling, directivity, all over frequency to
yield a good accuracy. VSWR can be computed in the spare
memory of a PIC used for a log amp IC power meter. If the
calibration test/adjustment is good, the overall device will be
more accurate and more versatile than any all-analog system.

Transformer based directional couplers are rare in amateur
literature but they do exist. Mini-Circuits has a line of them
Some hams will be familiar with "hybrids" from telephone
patches...which are a form of transformer directional coupler.
Transformers can be built to couple into KiloWatts and output
just tiny milliWatts. The log amp IC will accept levels from
mW to picoWatts over a 60 db dynamic range. A combination
power meter and SWR indicator can be built that will read,
broadband on HF, accurately from 1 KW down to a few mW
without having to switch anything.

No comments have been seen in regards to calibration of
the proposed project. If that isn't considered, then the whole
project is academic...a useful exercise but does not result in
a viable power or SWR meter. Hint: Think calorimetrically.
That's the way the instrument makers check their power meters.

On chopper-stabilized amplifiers: Fine for vacuum tube op-
amps where differential circuit grids varied in large numbers of
milliVolts over temperature and aging. Not much need with the
modern instrumentation-grade, low-noise ICs used for things
like thermocouple output voltages. Lots of those ICs out there,
only slightly more cost than "standard" op-amps. The romance
of tales from yesteryear on nifty circuits using tubes is nice but
no longer practical. [been there, done that a long time ago and
am very glad to be away from that]

The old "chopper" (a fancy vibrating reed) is very hard to get and
will probably cost an arm, leg, and assorted other body parts.
A substitute for a mechanical device is the CMOS switch and
there are a number of those from several IC makers. Faster,
lower-noise (all around), very broad-band, zero or extremely low
device offsets, practically noise-free to the op-amp or solid-state
circuit being stabilized. It's more fun to play with Dan Tayloe's
elegant innovation of a switch used as a "DC" mixer.

Nobody, and I mean nobody is going to get even close to 50 or
60 db dynamic range out of any diode detector. The successive-
detection logarithmic IC will definitely do that, accurately over a
very wide RF bandwidth and over a wide temperature range.

I've gotten a few more inquiries about my general coverage receiver design, so to make things simpler, I have created a WinZipped bundle that contains schematics, parts placement diagrams, and PDF files of all of the boards. This way, artwork can be printed directly on Inkjet or Laserjet transparencies, giving a good tool to use with photosensitive boards. The zipped file is 350KB, and you do need Adobe Reader to view the schematics and board information. Interested parties can feel free to e-mail me directly, and I will be glad to send the file out to you. I know that some of the folks out in NG land have had a hard time reading some of the GIF schematics that I had sent out, so all of you are welcome to shout me down! The next thing that I will be doing is adding another AGC loop ahead of the 1st mixer; after this addition, the receiver should be able to handle 2 or 3 volts of RF, but that is still a few months away.

Pete

And very few over the age of 60!

I'm 65 and my last chopper stabilized amplifier design job was in 1963.
My use was to amplify a 0.1 Hz signal with 0.005 Vp maximum.

In those days they were used to monitor very low level of DC [DC]
signals. Amplifiers were made by George Philbrick Laboratories.

A wide band amplifier with offset trimmed to zero and operating from a
well regulated power supply in a moderately temperature controlled
environment should meet the original needs. Use a high Gain-bandwidth
amplifier at least to 300 MHz.

I'm under 60, (by a few years) and I know and worked on chopper
stabilized instrument amplifiers for over eight years in the late 70's and
early 80's. These were double pole double throw mechanical choppers,
some 60 hz but most were 103 Hz units. 103 Hz being prime relative to
both 60 Hz and 50 Hz and their harmonics.
The application was an instrumentation amplifier to amplify the differential
voltage of two thermocouples in connected series opposing. Gain was
15000 and meaningful signal out could be .1 millivolts to an XYY plotter.
You do the math.

Nonsense. I'm not 60 (just 32h ;-) and know perfectly well what they are. I worked on vibrator-stabilized op-amps on the analog computers in college. Choppers were required to get the gain necessary for four significant digits. The servo multipliers and sine converters were the real hoot.

Paulo,

It was refreshing to hear something positive concerning American business. There has been soooo much bad lately.

I too am using Powerpoles. Just got through making a couple of cables using the connectors. If you've not tried them yet, I believe
you will be very happy with them.

All the best,

Vic / KE4QJK

Not in original boxes, but these look unused. Clean, shiny bases, no discoloration
in the envelope. I can't test them, but I'll guaranty them not to be DOA.
Have a look at them at:
http://www.angelfire.com/linux/tubesnstuff/images/4125A1.jpg
http://www.angelfire.com/linux/tubesnstuff/images/4125A2.jpg
AES gets $132.00 each for these. I'll take $100/obo for all 4.

1500. CI-V interface voltages mysteriously doubled

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-02-28 07:02:03 UTC
From: Dan Jacobson <jidanni@dman.ddts.net>
Message-ID: <874r6o51n8.fsf@jidanni.org>
Source record: 37353

Hi. I built the Icom CI-V interface http://www.g3vgr.co.uk/civ.htm so I could use http://parnass.com/tk2/ with my Icom R2.

Unfortunately communications are not proceeding. Perhaps the circuit produces too much voltage?

(For the R2 we use a stereo jack's middle and sleeve contacts, not the tip.) Positive voltage on the middle connector seen with the radio isolated from the circuit are, from the radio in "clone mode": 0.7 at rest, and 0.35 when transmitting as "clone master".

However, the circuit produces 1.4V at rest, and 0.7 when transmitting at 1200 baud. The radio must be right, so how did I end up sending twice the voltage I should towards to radio? What soldering flaw would do that this time, I say to myself. Though I've browsed on and on about this interface, all, I read about are "5V TTL levels". But anyway, the radio must be right.

Or, is the design working as intended, and perhaps I am cursed somehow because I use Linux? As for my RS232 port, at rest I find -10V on TxD, +10V on DTR, +10V on RTS. I am far away from parts stores, but have some old radios to pluck spare resistors if needed.

Anyways, for now the computer does not hear the data the radio sends out in 'clone out' mode, nor do I have proof that the radio reacts to the computer's commands. Help.

> is?

They may call it an auto-zero amplifier. Farnell lists a bunch of
integrated cirucit chopper amplifiers. The Linear Technology LTC1050
is listed as chopper stabilised CMOS operational amplifier, as are the
Maxim MAX422 and MAX430 and the Texas Instruments TI2652 and TI2654 as
well as the Intersil ICL7650.

Oddly enough, the National Semiconductor LMC2001 is not listed as
chopper-stabilised - it is, and very neatly - nor is the Analog
Devices AD8572 dual.

Once again, the use of antennas with which Part 15 gear (e.g., 802.11)
has not been certified *as a system* by the FCC is a violation of FCC rules.

Under Part 97 (ham) rules, that constraint does not exist and other
antennas can be used ... but you can't operate under Part 97 and
connect to a Part 15 network like the university WLAN that the
original poster was talking about ...

(There's a surprising number of video op-amps in DIP packages that will
directly amplify the R.F. side.)

From the DC POV, it's a bit pointless nowadays building a chopper amp (if
you insist, then the simplest is a '4066 as synchronous
modulator/demodulator :) when the likes of ICL7650 or OP177 are available .
Just amplify those diode voltages directly. But ... for good SWR's there's
still a big problem with diode AC to DC non-linearity at the bottom end of
the power range.
The linearising "compensator" circuit mentioned on the site is of only
little use with diode outputs below about 0.5VDC, as the compensator diode
'DC' comparison voltage is only a vague reflection of an actual input ACV
needed to give a particular diode DC output.
Good linearisation down to a mV or so, can be acheived using pairs of
matched (bench selected or IC packaged) diodes. One diode rectifying the
wanted RF. The other diode being fed with a variable AC voltage at say a few
hundred Hz. The DC outputs of both diodes are compared by a low offset
op-amp. This op-amp output then adjusts the low frequency signal voltage
level until DC balance is made.
As diodes are not really frequency sensitive, then for both to be giving out
(say) 1mVdc implies both are receiving maybe 100mVAC at their inputs. The
low frequency reference voltage can then be simply measured using normal
means such as a precision rectifier etc.
regards
john

Its Analogue, never seen a digital one? wouldn't have thought
a digital readout would be of much use, can't really dip a digit hi!
Standard sort of format, coils plug in the top of a small box with
a tuning knob calibrated in bands representing the coil ranges
and a small meter, probably about 6 or 7 years old but virtually
unused, was used once for a company project and then demobbed
could send a pic..

What with all the chopper discussion here, I just have to jump in.

First of all, Jason, I think you should check out the RF log detectors mentioned by others; besides Analog Devices, I believe you'll find that folk like Linear Technology and Maxim make some. But AD has some that will detect both phase and magnitude, and you _could_ use that to monitor not just the SWR but the complex reflection coefficient. That could be much more useful that just SWR.

On choppers and signal levels: What do you want the chopper for, exactly? I can imagine wanting an amp with good DC characteristics following a diode detector, but surely not for RF amplification in this case. But even for amplifying the DC out of a good diode detector, you don't need chopper stabilization for 10 millivolts of RF input; that should get you on the order of a millivolt of DC out, into a high impedance. A lot of op amps have low enough initial offset to handle that, and a whole lot more are stable enough that they'd work with a simple offset null adjusted once a year or less. A bigger problem is that you're wanting to operate a diode detector over a range that spans linear and logarithmic output versus input. That is, at 10 millivolts, the output voltage will be very nearly proportional to input power (or to input volts-squared), but at 1 volt and above, the output will vary linearly with input voltage. You'll be much better off to scale the input to match one of the RF log detectors, which will have guaranteed performance and a relatively easy to deal with output scale factor. Otherwise, be prepared to do some careful calibration work.

I used a chopper-stabilized op amp about ten years ago in a sensitive field strength meter. I needed that for low offset voltage and in this case low input bias current. It can "see" down to about 30 microvolts of input. That's around a microvolt out of the detector. That's WAY less signal than you'll have, and is only useful with a selective tank on the input. The chopper-stabilized amp was much easier to deal with than the drifty CMOS amp in the prototype version of the FSM. The biggest problem I had with it was from leakage currents around the chopper feedback pin; I had nailed input leakages by carefully guarding the input trace, but discovered that high humidity would really mess things up in the chopper stabilization part of the ckt. This was with the Harris part that Win mentioned.

With ANY solid-state parts around high RF fields, beware of rectification that can introduce difficult-to-trace offsets and other errors. If you're looking for low DC offset in your amplifiers, do

NOT let RF get into the inputs (or the power supplies). In some
cases, even a few millivolts can screw things up.

Cheers,
Tom

Hi everyone,

I'm looking for a source for positive photo resist used for sensitizing
copper laminate boards.
I know sensitized boards are available but I want to sensitize and use my
existing material.
TIA
Harry VE3MAL

The outer jacket is very thin on 1/2 inch.

>> Can anyone tell me good, cheap and durable ways to splice the
>> cable?

Two brass compression fittings and one UHF brass barrel connector.
You may (will) have to smooth down the threads to fit inside the
compression fittings. That's where having a lathe is nice, but a file
will do. Just make sure the finished surface is both smooth and
ROUND. You may have to add a bit of solder to the center conductors
of the 1/2 inch to get a tight fit inside the barell connector..

THEN, go down to your local electrical contracting store and pick up
some "flooded" heat shrink tubing. The stuff is a bit over one inch
inside diameter (unshrunk). It will shrink down tight on RG-8, so
it'll do the same with the connector and hard line.

The heat shrink tubing comes in four foot lengths at about $9 or so
"as I recall". Cut a piece long enough to extend about two to three
inches beyond the splice on each side. Slide this over one of the
pieces of coax *before* making the splice. After the splice is
completed, slide the heat shrink into place and then using a heat gun,
start at the middle and work out, shrinking the stuff tight enough to
see the shape of the connectors.

If done right you will see the flooding material (hot glue) squeeze
out both ends and all the way around. Just let it set...Don't stick
your finger in it as that stuff is *hot* and it won't let go. Please
don't ask how I know.<sigh>

>Without _any_ poly jacket, you need to worry about electrolysis and/or
>the PH of the soil. If it were me: I'd bury it in some black poly pipe.
>'Twould be a feat to stuff in a looooooong run of it...

It's actually not all that bad...Use lots of wire pulling soap..The
ugly yellow stuff that comes in a pressurized can...sliperier than
snot on a door knob.

One person can do it, but it's safer (for the coax) if you can get two
of three. You need to get the pipe out straight, so it might have to
spend a day or two in the warm sun getting straightened a bit at a
time.

You need to be careful getting the coax out of the roll and
straightened before going into the pipe. It's real easy to pull a bit
too much coax while forgetting to watch the roll. As you've found,
that stuff kinks easily. That's where the extra help comes in handy.

>
>> Finally, does anyone care to share any hard-won experience, or
>> pointers to complete information, or whatever?

> http://www.jonz.net/W3DHJ/catvhardline.html
>

The only thing I'd change with the 3/4 inch is using brass compression fittings and UHF barrel connectors.
http://www.rogerhalstead.com/conn.htm Moisture is not usually a problem in the 3/4 inch as it can't migrate even if it does get in at the connector, so a good weather proofing of the connection should do the job. You can use adapters for N connectors.

1518. Question on backpack 40m antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-01 06:28:53 UTC
From: Bert Herald <bert.herald@worldnet.att.net>
Message-ID: <FqY7a.75467$zF6.5360348@bgtnsc04-news.ops.worldnet.att.net>
Source record: 37371

I love to backpack my gear to the top of a hill overlooking my town, which makes a great DX spot. I run a Small Wonder Lab's SW-20 20m CW rig off of NiMH batteries and it works great. The antenna I use is an inverted vee dipole, with the center supported by a 20ft pushup. The hill is so steep in almost all directions that I seem to have a decent low angle of radiation, or at least low enough to get the job done (have worked lots of DX and had great signal reports).

Here's my question: I need a decent 40m antenna for the same hilltop (to use with my upcoming SW-40 and RockMite 40 kits). I can't string enough wire to make a 40m dipole work. I'd like to use a vertical, but my past experiences with verticals at low power have not been successful (but I've always had lousy ground and no radials). I have a hamstick and a magmount, but it is useless up there. Does anyone have an idea for a great 40m antenna that is lightweight (being light is important!) and easy to assemble that will get me heard? Preferably home-brew, as I'm not looking to spend a lot of money. Any weblinks on designs that work would be appreciated too.

Thanks,
Bert WF7I

1519. Source for "copper clad" boards

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-01 06:32:47 UTC
From: Bert Herald <bert.herald@worldnet.att.net>

Source record: 37372

I'm looking to start dabbling with building my own RF circuits and would like to get a bunch of this "copper clad" material that you can solder parts to for the "dirty" construction style. Where do you get this stuff typically? Is there a bargain-rate place somewhere to order, or is it pretty cheap normally? I've never seen any of it at "The Shack".

Thanks,
Bert WF7I

1520. Torroids, chokes, and other RF toys

Newsgroup: rec.radio.amateur.homebrew

Source record: 37373

OK, here's a final question. "The Shack" also does not stock torroids or RF chokes anymore (at least not that I can find). I'd like to have a grab bag of these and many other parts so that I can play at building various circuits for fun. Any suggestions of a decent supplier? Not looking to spend 100s of dollars, but would like to have a wide variety of parts on hand.

Thanks,
WF7I

The cheapest place I have found is Goldmine electronics.

http://www.goldmine-elec.com/

Search for the key words "copper clad" to see what they have.

I -have- seen it at the Shack, but the stuff they have is amazingly low quality. If by "dirty" you mean "Manhattan", their stuff just crumbles when you try to make pads.

I've found hamfests to be the best source. Although DigiKey, Mouser, and almost anyplace like that has the stuff, their prices are enough to put you off homebrewing. Someone here mentioned Goldmine Electronics, and I've heard that mentioned by others, but I haven't tried them. Seems like All Electronics also had copperclad at sensible prices, but again, I haven't tried them.

What I do is keep an eye out, then when I see something at a decent price, I buy up a few years' supply. Often scraps from places that make commercial boards are available almost free and are often quite nice sized. I often pick up pieces about 6 or 8 inches by 3 feet for about a buck, sometimes less. You can cut a fair number or boards out of that.

Of course, if you are going to Dayton, there will be plenty of suppliers. Far Circuits often has plenty of scrap pieces almost free and they always show up a Dayton.

The Arizona ScQRPions (http://www.extremezone.com/%7Enk7m/sqrppage.htm) has plenty of members near you, and they are mostly avid builders, so if there are good sources local to you, they would know.

https://server108.hypermart.net/nelniech/nelniech/pcboard.html

this is the page with the board, click on link at bottom of page to
get to main page of this outfit. or just go here.....

https://server108.hypermart.net/nelniech/nelniech/nelniech.html

cheaper than mouser but the board is of lower quality, mouser sells
fr-4 I believe and this is probably not as good but its good for a
beginner. You can buy some big pieces here too if you have access to a
shear or can cut it well with a saw or scoring tool.

Dan's Small Parts and Kits (http://www.danssmallpartsandkits.net/) often has collections of popular sizes and mixes. However, he only does business by snail mail so expect at least a two week wait.

W8DIZ (http://kitsandparts.com) has very good prices on popular mixes, but he doesn't always offer collections of various mixes. However, I suspect if you sent him an email he could be talked into it. Even so, for twenty bucks, you could have a several years' supply of the more popular mixes from him so you might think that way. Amidon and Palomar Engineers both have all the sizes and mixes, but their shipping is high enough that it's worth just buying handfuls from Diz unless you need a lot of odd mixes. I would suggest that T50-6, T50-2 and FT50-43 would cover 90%+ of what you need unless you are really into miniaturization and want smaller stuff, or are building high power equipment and need larger stuff, or are really into 160 or VHF and want odd mixes. The only other popular mixes for ham work are -7 which has a slightly better temperature coefficient than -6 and so is used for VFOs, -1 which helps reduce the number of turns you need on 80/160, and -10 which increases the turns you need (and thus your control of the inductance) on 10. Plus, the type 61 ferrite which is used sometimes in transformers (although 90% of the time people use type 43 ferrite).

The CI-V interface uses an open collector bus, so the voltages with the radio disconnected from the circuit are not really relevant. I'm actually surprised that 47K didn't work, but it is way higher than I would use. With only one radio, you probably could go down to 470 ohm or lower, but that would prevent more devices from being connected in parallel (assuming that they all had internal pullups, sounds like your R2 doesn't have an internal pullup).

Each transmitter on the CI-V bus sinks current to drag the bus voltage down to a TTL "false" level. Somebody on the bus needs to pull the bus up to a TTL "true" level when nobody is talking. Most open collector devices can sink a healthy amount of current so the size of the pullup resistors is pretty non-critical unless you have a lot of devices working in parallel. 4.7K is light enough you probably could put a bunch of devices on the bus. Personally, I'd probably go a little lower if I knew I was only going to use one radio. With a little more current there would be a little better noise immunity, but probably not enough different that you'd notice, and you would be asking the radio to sink a little more current, which would heat things up a little more in the tiny radio.

Do they really! well just shows how long I've been out
of it hi!! fancy having a digital readout of the freq I
wouldn't have thought it worth it, after all a GDO reading
is a very broad sort of measurement! affected by all sorts
of things.. when I needed to know where it was roughly
I just held it near my counter..
But sadly no, no sort of digital readout at all on this box!
pure utility :)
Without struggling up into the loft I suppose it covers from
a few mhz up to about 200mhz over about 6 plug in coils

I fixated on the toroids and missed the "chokes and other RF toys" part.

DigiKey has a good selection of inductors and chokes at sensible prices. I keep few of them in the parts drawer, however, preferring to make what I need from toroids rather than stocking a wide range of values.

DigiKey also has a few synthesizer, prescaler and other RF chips, but in general, there supply of RF parts is pretty weak. I like them, though, because their service is astonishing.

Dan's has a changing supply of almost anything the homebrewer needs. Usually, if he has it, the price will be very good, but you can't count on him having anything.

RF Parts has a good selection of, well, RF Parts. If you need an actual RF transistor for a final or something, they are about the only place to go. Unfortunately, their prices reflect that. They used to be the only place for dipped silver mica caps, but now DigiKey carries them.

I often find useful things at good prices from places like B.G. Micro or Mendelsohn's. Both of these places have inventories that change with the wind, and prices that may be very good, or not, so you need to know what you are looking for. B.G. often has a good selection of MOSFETs that can be used in finals at very good prices. Also, they usually have some sort of a deal on LCD displays. But you need to know what you are looking at. For example, their prices on crystals are typically almost twice DigiKey's.

1535. Why are SWR meters designed for low SWRs?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-01 20:08:05 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0303011208.4bb127c9@posting.google.com>
Source record: 37388
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I would particularly like to hear what Reg, Roy, and Doc have to say.

I'm working on a super SWR/wattmeter for a graduate school project. Why are the SWR meters (MFJ, Radio Shack, built-in) set up to provide good resolution only at low SWR levels? The reflection co-efficient (reflected voltage divided by forward voltage) is .5 at an SWR of 3. But for all of the SWR meters I have seen (including my cross-needle MFJ 945E), an SWR of 3 is NOT in the middle of the scale but well past it. In fact, the middle of the scale is usually an SWR of more like 2. But a transmitter SWR under 2 is good enough. Does it really matter if your SWR is 1.0 or 1.1? However, when your SWR is high, it would help to know if you are tuning in the right direction. On my SWR meter, it's hard to tell the difference between an SWR of 5 and an SWR of infinity. I would rather have the good resolution at high SWR levels, and that is the inspiration for my project. I may seem strange to you, but I would like to know if I have lowered my SWR from 15 to 10. At least I would know I'm going in the right direction, and I would know if I passed up the low SWR point.

An SWR of 5 corresponds to a reflection ratio of 2/3. An SWR of 2 corresponds to a reflection ratio of 1/3. Showing an SWR of 5 should be as easy as showing an SWR of 2, but an SWR of 5 is usually portrayed as a hair away from infinity. An SWR of 1.5 corresponds to a reflection ratio of .2 while an SWR of 9 corresponds to a reflection ratio of .8. But in my MFJ meter, an SWR of 1.5 is easily readable, while an SWR of 9 is indistinguishable from infinity. An SWR of 1.2 corresponds to a reflection ratio of .09, and an SWR of 21 corresponds to a reflection ratio of .91.

So why do SWR meter designs have to be skewed so greatly?

Most simple swr (wattmeters) use components that work on a log function. The diodes in them function mainly in the so called square log area of voltage/power. If you look at the scales of many analog meters any that are not measuring power or resistance do not have linear scales simply because it is easy and cheaper to make them that way. ONe other thing is that when the SWR geto over 2 or 3 to 1 then it is high enough to do something about.

Okay, Ron. Obviously the *dip* metering is shown by an analogies
meter; it's only the frequency of the oscillator that's shown
digitally. Provided this display shows a sample of that, sniffed from
the output stage of the oscillator, it's an accurate reflection of
precisely what frequency the dip is taking place at and extraneous
factors that can 'pull' the oscillator won't be a problem. Analogue
dial read-outs can't compete with that degree of accuracy, obviously.
They're merely an approximately-linked representation.

Hi,

I would like to know how to check the frequency of my ic-730 receiver.
I have a mfj antenna analyzer and a frequency counter. I read somewere that
it is pretty easy using the zero beat technique, but I wonder how we do it.
In what mode does the receiver should be set? When do we know that we are on
the right frequency?

Thanks a lot for any help,

Francois,

Hi Jason,

Why? Because it is both easy and reveals the region of most interest
to the average user.

Want to change that? Add another diode across the meter's leads.

Some Icom radios such as the 746 won't give a good logic "high/true"
into a load as low as 4.7k plus the base-emitter drop of the receiving
transistor. It may be necessary to increase that base resistor to say
22k or more, and perhaps to use a higher-gain transistor.

I found that out using Ekki Plicht's 'CI-V Commander' software, which is
excellent for trouble-shooting and monitoring activity on the bus...
though it only works under Windows:

1544. Re: What is zero beat?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-01 23:31:37 UTC
From: Dan/W4NTI <w4nti@NOSPAMmindspring.com>
Message-ID: <b3rft6bus1@slb5.atl.mindspring.net>
Source record: 37447

Zero beat is when the receiver is tuned exactly dead center of the received CARRIER.

Find yourself a carrier. Say from your 'calibrator'. It should show up every 100kc or some of them do it every 25.

Turn your VFO slowly across the carrier. You will note that the frequency will slowly change. If you tune it very slowly you will find a place that the tone goes lower and lower until you can hear only a very low frequency tone...then nothing. And as you continue to tune the tone will begin to rise again.

Zero Beat is when you hear the lowest tone.

This can be done in either SSB or CW mode. It will not work in AM or FM modes.

Dan/W4NTI

Jason,
The usual SWR meter scale is not linear at all (but logarithmic). And, as Cecil said, most people don't care it they can distinguish between a 5:1 and a 20:1, they would rather see what is happening at the other end of the scale. Personally, knowing if I have an SWR between 10:1 and infinity doesn't interest me as much as 'where' the SWR is between 1:1 and 5:1. Once it gets over 5:1, I figure I'm in the wrong 'ball park' anyway. Of course, if you want to, you could always recalibrate the meter's scale for the high end, but how often would you use it?
'Doc

Source record: 37451

The problem, of course, is that your rig's IF probably whacks out anything below 100 Hz or so. This makes it really hard to hear zero beat.

HOWEVER, your Icom probably has a CW-R mode. Tune the carrier that Dan mentions as if you were tuning a CW signal, and switch between CW and CW-R mode. When the 2 sides have the same tone, you are "zero beat". It's not too hard to get within about 5 Hz or so this way. Trying to actually hear the zero beat will be tough within a hundred Hz or so. Keep in mind that your IF wants to pass only the part of the signal responsible for intelligence, so for SSB this is about 300 Hz to 3 KHz and for CW, about 300 to 800 Hz. Obviously, you may have installed filters to make this narrower.

A caution about using CW mode to try to zero beat. When you are using CW mode, your radio will indicate the carrier frequency when you hear a tone of 600-800 Hz, depending on your radio. At zero beat, the indicated frequency will be that far off.

Unless your radio has an audio chain that takes out low frequencies (common if the radio can receive FM as well as CW/SSB), it's easy to hear the difference between 2 carriers. If you are comparing a signal generator to, say, WWV you should be able to hear a low frequency thumping as you get close to zero beat. This is especially effective in AM mode.

With an all mode radio, however, the audio often chops low frequencies so you aren't bothered by the PL tone on an FM signal. This is why this doesn't work if you have a radio that can receive FM.

Don't forget that many radios shift frequency about 800 Hz when going from
SSB to CW.

1550. Re: Mac software availability?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-02 01:07:46 UTC
From: Bob Camp <bob@cq.nu>
Message-ID: <CPc8a.642362$HG.118924448@news4.srv.hcvlny.cv.net>
Source record: 37453

Hi,

A lot depends on what kind of Mac you have. They have been through several generations of machines and operating systems. More or less there are:

1) Machines made back in the 1980's based on early Motorola CPU's
2) Machines made in the 1990's based on more modern CPU's
3) Stuff made in the last few years

In addition to the hardware changes there are ten different operating system revisions for the Mac. The oldest machines had their own stuff and when the newer machines came out the operating system changed a lot. Software written for the new machines and operating systems will in general not run on the older 1980's machines.

Recently they came out with a whole new operating system called OS-X. It will only run well on a fairly new machine. Again same problem - software written specifically for the new machine will not run under the old operating system(s) on the old machine(s).

What to do .....

If it's a fairly new machine then consider upgrading it to the latest operating system and start downloading software. There's a ton of it out there.

If it's an older machine then it's probably not worth upgrading.

Take Care!

Hi Pete,

I went to the web site, but only one of the four files would download.
I got the zip file, but got a WorldNet error page from the other
three. Since it looks like everything is in the zip file, I should be
ok, but you might want to delete the other three links to avoid
further confusion.

Thanks,

> Jason Hsu, AG4DG

==========

Jason,

There's a strict mathematical relationship between the output voltage of a so-called SWR bridge, the linear meter deflection of a moving coil meter, and the SWR which causes it.

So there's nothing anybody can do about how the meter scale is graduated such that the needle indicates an SWR between 1 and infinity.

If you should feel the need for more sensible, meaningful, graduations then erase all thoughts from your mind about SWR and calibrate the scale LINEARLY from 0-to-1 (full scale deflection) in terms of "Magnitude of the Reflection Coefficient".

Actually, there's no such thing as an SWR meter. The name is a misnomer. In most situations there isn't even a transmission line to measure it on.

Of course, the little box between transmitter and tuner does perform a valuable function. But a far more appropriate name is TLI = "Transmitter Loading Indicator". And it needs no scale graduations.

That you have already discovered little useful meaning can be attached to indicated SWR values (eg., the difference between 9 and 11) is itself sufficient evidence of no need for scale markings.

The magnitude of the reflection coefficient is not of much use either. Nothing can be calculated from it because phase information has been willfully discarded.

Green (good) and red (bad) bands would make a colorful finishing touch for your project.

In view of your description "super" power meter you should be warned that the most inaccurate procedure in RF engineering is the measurement of power. Consider it essential to check accuracy by making entirely independent measurements of the power dissipated in say a 500-ohm load on the antenna side a 50-to-500 ohm ATU.

You may find program SWRMETER of interest.

I did fix those bogus links, and added a couple of others, including a mini-tutorial on PLLs and an active multiband loopstick antenna design. I will be adding a few other things, as time goes on. I would like to upload my redesign of Marshall Leach's high performance stereo preamp, but I need to get his permission first. About that zip file.....I have updated it. You will notice that the bandwidths of the filters on the Rx board were not shown. That has been corrected. Also, the 30MHz reference frequency for the DDS and the 4MHz frequency of the PIC's clock crystal were not shown. This has also been corrected on the new zip file. All others that have e-mailed me, and gotten the old zip file, can now go to http://home.att.net/~n.gianakopoulos/wsb/html/view.cgi-home.html-.html This is my new website, and has all of the updated files. Thanks for the bandwidth, folks. If you do go to my website and you have questions, feel free to give me a shout!

Pete

The meter scale may favor *indications* of low VSWR for the reasons already posted -- but that doesn't mean they can be believed.

The directivity of the RF coupler used to drive the metering circuits often is not better than about 26dB, which limits fairly accurate "VSWR" measurements to about 1.4:1 (and progressively more inaccurate at lower indicated VSWRs).

There are many "standard" connectors in that size range. More info,
and a picture of the connector on your website, would help a great
deal.

Alternately, search Newark, Mouser, etc. or look up your camera model
for the connector type.

Happy trails,

> updated it. You will notice that the bandwidths of the filters on the Rx
> board were not shown. That has been corrected. Also, the 30MHz reference
> frequency for the DDS

Pete as I emailed direct to you I don't quite understand how the DDS
clock frequency
can be 30mhz, as the dds output must go as high as 40.7 mhz to satisfy
the Nyquest criteria
the clock has to be at least 81.4 mhz. The 9852 dds chip does have a
clock multiplier/ pll, but
I don't think the 9851 does.
Also is that a bpf or a lpf on the output of the dds? (If it is a bpf,
it is a rather special
design to go from 10.7-40.7 mhz and have steep enough sides to cut off
the higher order
harmonics). I would have used switchable bpf's on the output of the
dds, similar to the
ones on the receiver input. Do you have access to a spectrum analyizer,
and if so, have you
checked the output of the DDS?

Also I have seen a design that used the DDS as a divider
for a PLL. In this lo a reference in the neighborhood of 1mhz is used
and the output of the pll
is feed to the dds as the clock, the dds divides this down to the
reference frequency. This design
seems to have an advantage in that the DDS can operate at half the clock
frequency required
for it to generate the lo directly and the pll cleans up the aliasing
crap.

Well, Jason asked a very general question on the "why" of
making commercial "SWR" meters. The "why" is probably
related to a minimum of design time expended on absolute
accuracy versus a maximum of product profit in production.
:-)

>If you should feel the need for more sensible, meaningful, graduations then
>erase all thoughts from your mind about SWR and calibrate the scale LINEARLY

>most situations there isn't even a transmission line to measure it on.

True... :-) Industry uses the term "VSWR" or "Voltage Standing
Wave Ratio" (commonly pronounced "viz-war") as more indicative
of the common measurement method with some form of
directional coupler gizmo. For some really old, old, and tiring,
tiring ways to measure there is the ever-loving "slab-line" with
e-probe which does use a transmission line section but
measures only the electric field...hence the VSWR term origin.

>Of course, the little box between transmitter and tuner does perform a
>valuable function. But a far more appropriate name is TLI = "Transmitter

>The magnitude of the reflection coefficient is not of much use either.
>Nothing can be calculated from it because phase information has been
>willfully discarded.

True enough...but a coupling device (such as an antenna tuning
unit) might be optimized through considerable, focussed tweaking
while looking for a minimum reflection. :-)

Those who want to optimize their power transfer into an antenna
should take the time to measure antenna impedance or
admittance over frequency. VSWR can be derived from that
with as much or more accuracy than using directional couplers
of any kind.

>In view of your description "super" power meter you should be warned that
>the most inaccurate procedure in RF engineering is the measurement of power.

Oy...I have to disagree with that!

RF power measurement of an unmodulated carrier is as accurate
as the power meter's calibration. Such calibration is usually
based on calorimetric standards which are better than 1%.
In-use accuracy of RF power depends both on the power meter's
intrinsic calibration with a perfect source but also on the effect
of the imperfect RF impedance of the power sensor at that
frequency. Such sensor imperfections can be measured
independently (impedance quantified) and that used to determine
the overall inaccuracy.

Where the alleged inaccuracy comes about, it is in trying to
measure power output of an RF source in-line with an unknown
impedance. Not only is this highly dependent on that impedance
(or its inverse of admittance) but it is also dependent on the
RF source's ability to supply power into non-optimum
impedances...i.e., the source's source impedance plays a part
in that.

>Consider it essential to check accuracy by making entirely independent
>measurements of the power dissipated in say a 500-ohm load on the antenna
>side a 50-to-500 ohm ATU.

A partial "calibration" of a finished "SWR" meter can be done
with different non-reactive resistances. If the reactance of such
resistors (usually made of unobtainium) is nil, the "SWR" is
determined solely on the magnitude components. No phase
component of the load impedance is there to mess up thoughts.

Unfortunately, a finite human-built "SWR" meter will have
assorted reactances which react over frequency, independent
(and perhaps in spite of) of load characteristics. Those things
can mess up one's day. There ARE answers to all that and
ways to isolate them or make them relatively inconsequential

but that leads to unfriendly territory of militant "4-ports" having
S-parameter-like equations. Hewlett-Packard has a number of
very nice application notes addressing that in detail as part of
their early push on their network analyzers. Skullwork needed
for understanding but the answers are out there.

Myron,

Thanks for the info. I was kind of leaning this way as well. I've got a 40m hamstick, so for a few dollars I can buy a second one and rig together a feedpoint. Even though I wouldn't have much height above ground it might be the easiest solution. Or adding traps to the 20m dipole as the other fellow suggested.

What's a "direct-conversion" receiver? If you mean there's no IF
involved, then nothing's converted, directly or indirectly.
Clarification, please.

Source record: 37471

Actually, the AD9851 has a (X6) PLL multiplier on board; that is how I can clock it at 180MHz by using a 30MHz reference source. As far as Nyquist criteria.....in theory is works, but my experience with the Synthesizer Group at Rockwell has shown me that a DDS shouldn't really be used at more than 33% of its clock frequency. 25% seems to be the "sweet spot". Also, as you probably already know, DDSs have many low level artifacts that remain at the same amplitude, regardless of clocking frequency. I think as the number of bit resolution in the DDS is increased the carrier to artifact ratio does improve. I do have a 9852 eval board, and it seems to be much cleaner than the 9851, but that current draw!
About that filter.....yes, it is a bandpass filter, and the skirts are not super steep, but it does the trick, because the low-pass filter after the RF amplifier helps quite a bit. This unit is capable of putting out +17dBm, but with the component values shown, output varies from +7dBm at 10.7MHz to +8.5dBm at 40.7mHz, being very smooth in output between those frequencies.
I do have an 8558 Spectrum Analyzer, so I was able to characterize the unit for spectral purity. The 2nd harmonic is -35dBc, which is fine with this receiver, because the filters at the front end of the receiver will reject the resulting spurious responses. Think about designers who use square wave injection at the LO port of a diode ring mixer, which, by the way, I am using.
For critical evaluation of the DDS, I used an HP 8563 Spectrum Analyzer, with Phase Noise Utility. At a 7kHz offset, the phase noise measures -124dBc, which isn't bad, considering that I am using a packaged Epson oscillator as the reference. If I were to use a discrete crystal oscillator, with a 200Hz crystal filter at its output, the phase noise could possibly be better.
Most of the low level artifacts measured between -65dBc and -75dBc. There were a couple of those stationary artifacts, that when you tuned the outpur signal through them, would increase in amplitude to -54dBc.
This DDS is in no way as clean as some of the PLL designs that I've built over the years, but still.....it's pretty cool, having everything on that small board. I will be uploading a later version of the code that allows you to set the I.F. offset on the fly, drives Optrex 2-line displays, and has tunable memories. I just need to test this code a bit.
That last idea that you referenced sounds good; I was thinking of an approach, using one of my old PLL boards, having the divide ratio fixed, and using the DDS as a variable reference. This way, the PLL would act as a tracking filter. There have just been so many kettles on the fire, I just haven't had the time to put into it yet.
On a final note.....I do appreciate your input; it is these things that help everybody along. I know that I mentioned this in our private e-mail earlier this afternoon, but I will mention it here. I will

be uploading a high output version of the ARRL noise source, a random audio noise source, and a general purpose NE602 based SSB Detector that can be used with boatanchor receivers. This is the same detector circuit that I use in my receiver, and is tunable from 480 to 610kHz, using the specified Toko RMC502182 transformer.

The direct conversion receiver is basicly just a product detector
operating at
the air frequency. Perhaps direct conversion is a poor term, but what would
you call it?

Direct conversion from rf to audio. RF mixed with Local Oscillator + filter
to yield audio. These have been around since the 1960's, when I guess solid
state mixers and amps got popular. Surprised you have never heard of them.
May be wrong, but direct conversion receiver applies only to solid state, not
the old tfr tube stuff. If I am wrong, sure someone will let me know.

Many years ago (I don't remember the issue) there was an article in QST
involving an image reject direct conversion receiver using tubes. I
think it
used a pair of 6SB7Y's. It used that old B&W audio phase shift network
(housed
in a metal tube can with an octal base) and an rf r-l-c phase shift
network. What this
is is sortof a balanced modulator run bassackwards to mix the incoming
signal with
two local oscillator signals 90 degrees out of phase. It generates two
audio signals
90 degrees out of phase which are combined in the B&W network. The
result is
a single signal direct conversion receiver. There have been solid state
versions in QST
more recently, but it was first done with tubes. The terminology was
different then,
but (to quote the Bard) " a rose by any other name ..... "

This will work but the feed point impedance will be very low, on the
order of a few ohms. A simple L network will match it fine. See any
ARRL handbook. Efficiency will be pretty low, too.

Gary:

I think you meant TRF not tfr. TRF has both tube and solid state variants: solid state receivers using the ZN-414 type chips are TRF's. And you can very easily build a tube type DC rx. Doug DeMaw published a tube tranceiver with a DC receiver in QST many years ago.

The difference between a TRF and a DC (direct conversion) is that TRF's usually have a diode type detector for AM reception, whereas DC's have a product detector making them useful for CW and SSB.

If you want to see the effect of tuning when SWR is high you should be watching reflected power not SWR.

Of what possible use is swr OR reflected power to an HF amateur?

He needs to know only whether or not the transmitter is loaded with a
resistance of approximately 50 ohms.

Anything else is just something to waffle about by SWR meter salesmen and on
newsgroups. ;o

|
|So why do SWR meter designs have to be skewed so greatly?
|

Most of these things are actually measuring reflection coefficient and
displaying it as something else: SWR.

In the old days, circuits such as the Monimatch, etc. were set up with
a front panel pot that adjusted the meter sensitivity. You switched
to the forward position and adjusted the meter to FS. This
"normalized" the meter to account for the incident power.

When you switched to reverse, you were reading the normalized
reflection coefficient (rho), but the meter face was calibrated in SWR

where:

SWR = (1+rho)/(1-rho) Eq.1

So with SWR = 3:1, the meter reads half-scale. If the builder wants to normalize the forward reading to something other than one (FS), the reverse reading will move accordingly. Now you have to get inside the head of the designer.

In your case, you seem to want to look for small changes in a big number. (Going from SWR 15:1 to 10:1 is the difference between 0.875 and 0.818) Clearly, a piece of cake for a DVM but rather difficult with an analog meter. (Hint)

OK, and how is he supposed to find that out *without* the SWR meter?
Please don't say the antenna analyzer.

> Anything else is just something to waffle about by SWR meter salesmen and on
> newsgroups. ;o

From the amount of your anti-SWR meter posts, one would conclude you're
an antenna tuner salesman.

SWR meter is a useful tool because it provides a quick and cheap visual
indication of the antenna resonance, over short and long periods of
time. The user is able to determine not only whether his signal is
making it to the antenna, but also whether there is a change in
performance which may indicate a problem with either the antenna or
something else in the output path.

Well, quite. That one of Clinton's was presumably unsmokable or else
bloody hard to light. I somehow think flavor might have been a bit
tainted as well. Shame really - certainly to those of us who
appreciate a fine cigar and know which orifice it rightfully belongs
in.

Just to clarify a bit. The new book is called "Experimental Methods in RF Design" and is by Wes Hayward, Rick Campbell, and Bob Larkin (all hams of course). It's brand new from ARRL, not even in stores yet I guess.

The circuit I'm working on is on page 1.8, Fig. 1.9, "Direct conversion 7-MHz receiver using two integrated circuits". I can't get the Colpitts oscillator to oscillate right now. I've heard this oscillator can be real finicky.

If anyone is working on this, or has bought this book and has thoughts about the book, I'd be real interested in the feedback.

OK, OK, so the diode detectors operate in the square law region and the forward/reverse power meter scales are logarithmic.

However, I still can't understand why people aren't interested in SWR measurements above 5. Don't many HF operators use nonresonant antennas? What about those using a random wire? G5RV? Or a mobile antenna with bandwidth narrower than Ally McBeal's waistline? Come on, I don't see how anyone can hold the SWR under 5 over the entire 160m or 75/80m bands, especially those who don't have room for a 65-130-foot vertical antenna or a 130-260-foot dipole as well as those who use one antenna for multiple bands.

How do you keep your transmitter SWR under 5 for the entire band? Come on, SWR bandwidth is so tight on 160m and 75/80m that it would be easy to miss the resonant settings when twisting those tuner knobs. I would think you would want to know when you have brought your SWR of 20 down to single digits so that you know it's time to slow down your knob-twisting.

I'm with Roy. Once you determine your desired coupling ratio, that will dictate the turns ratio. 10:1 for 20db, 31:1 for 30db... You then need to choose a core material that yields enough reactance at your lowest frequency (i.e. 4x Zo) with those turns. Then choose one large enough to handle the power.
Regards,
JE

No, an autodyne is another name for a receiver with a regenerative detector.
Perhaps 'syncrodyne' might be better, since a seperate oscillator is used.

I'll show my ignorance here - is there a convenient way to calculate the temperature rise in the core that Jason originally referred to? I'd end up pulling out an old textbook and calculating Grashof and Nusselt numbers for laminar flow from a vertical plate, and then finding the thermal equilibrium
point. I imagine that there's an easier method for standard components.

Thanks,
- Bruce/ND8I

Well OK. I'll help you with your homework. :)

First let me address one of the things I've read here. "Most SWR meters are square law". Well- that would be nice but it's not true. Square law implies a linear detector output(voltage or current) vs. input power. Square law power meters therefor have linear scales. Most amateur power meters operate in the linear region of the detector. This is easy to verify by looking at the meter scale. The half scale deflection indicates one forth the fullscale power. Doubling the measured current(voltage) yields four times(two squared) the power. The meter movement responds linearly to current, but the scale is anotated as the square of its input.

Why are SWR meters most accurate at Zo? Two reasons: They are calibrated a Zo, that is they are nulled with a Zo load. Second, there are three error terms when measuring reflected power with a directional couple(ie SWR meter). They are source match error, load match error and directivity. As you move further from Zo the source and load match errors grow. At Zo these go to zero and you're left with the directivity error term only.

Regards,
John

AFAIK, OS Electronics only has negative resist. The same goes for You-Do-It Electronics in your neck of the woods, Gary. (And if I'm wrong on this, please refer me to the right information!) Indeed, after some extensive looking I've not found a single supplier of liquid positive resist in the US willing to sell to a hobbyist in hobbyist quantities, although there are UK suppliers of the stuff (who won't ship across The Pond). In my college days, more years ago than I care to recall, I used to use AZ111, a positive photoresist that was made by the Shipley Company in Newton, MA, as well as Kodak KPR, which was a negative photoresist. (And yes, the solvents in both resists were nasty, which may explain the persistent rash I've had all these years... And while AZ111 was developed in a lye solution, KPR was developed in trichlor, which is *really* nasty.) I haven't been able to find either, although the negative resist I can buy appears somewhat similar to KPR. All the positive photoresist products I've seen that are suitable for hobbyists are copper-clad boards pre-sensitized with dry photoresist film. If anyone knows of a supplier of liquid positive resist willing to sell to a hobbyist in the US, I'd like to hear from you.

Heyo Cecil,

As a side-note on the Bruene circuit, perhaps one of the first
uses of that magnitude-phase detection circuit is in the old
US military transmitter T-195 of the AN/GRC-19. The T-195
was designed with an integral automatic antenna tuner by
Collins Radio back in the 1950s.

A full theoretical description of that automatic tuner, complete
with phasing diagrams, practically a short course in how such
things work, is found in TM 11-806. That Technical Manual is
available free for download at August Johnson's website at

http://www.kg7bz.com/Manuals.html

The PDF download is a whopping 33 MB in size but it may be
well worth it to explain a tube-oriented HF transmitter in some
considerable detail. The final amplifier voltages and currents
are shown in diagrams above and below tuning, a good
tutorial on how those things operate. There's another TM there
on the accompanying R-392 HF receiver, also a Collins design.

TM 11-806 also has a lot of detail on construction of the Bruene
circuit and its directional detector. No dimensions but one can
get a feel for the size of things in comparison to other familiar
components. Strictly speaking, the Bruene circuit is a detector
but in the T-195 the detector output is made to a servo amplifier
in a bridge type decision circuit. Note: The T-195 can auto-
matically tune its final as well as the antenna tuning circuit.

Worthwhile meters aren't calibrated in SWR ratio anyway. They're calibrated in watts forward and
reverse. You'd have to calculate the ratio if you were interested. I'm not. I just want that reverse wattmeter
reading to be low.

The reflected power reading serves to confirm that the antenna system is tuned and working as planned.

Other than that, I agree

Not offhand, but here are a few examples of Bush's 'ouput' that
somebody sent to me.
I find it pretty scary to think somebody like this had his finger on
the button of the world's largest nulcear arsenal.... :-(

At a public address in Nashville, Tenn., in September, Bush
provided one of his most memorable stumbles. Trying to give
strength to his case that Saddam Hussein had already deceived
the West concerning his store of weapons, Bush was scripted to
offer an old saying: Fool me once, shame on you. Fool me twice,
shame on me. What came out was the following:

"Fool me once, shame ... shame on ... you." Long, uncomfortable
pause. "Fool me - can't get fooled again!"

"I want to make sure everybody who has a job wants a job."
- George Bush during his first Presidential campaign.

"If we don't succeed, we run the risk of failure."
....George W. Bush, Jr.

"When I have been asked who caused the riots and the killing in LA,
my answer has been direct & simple:

Who is to blame for the riots? The rioters are to blame.
Who is to blame for the killings? The killers are to blame.

....George W. Bush, Jr.

"You don't need to be smart to be president"
--Republican Congressman J.C. Watts - said at a February campaign
appearance on Bush's behalf. Washington Post, 6/11/00

"I think anybody who doesn't think I'm smart enough to handle the
job is underestimating."
--U.S. News & World Report, April 3, 2000

"Rarely is the question asked: is our children learning"
--Florence, SC, Jan. 11, 2000

1618. Homebrew Website Up and Running

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-04 06:07:16 UTC
From: Pete KE9OA <n.gianakopoulos@worldnet.att.net>
Message-ID: <ooX8a.10172$Uy4.843831@bgtnsc05-news.ops.worldnet.att.net>
Source record: 37321

Hi Folks,

Hi Folks,
I've got my website up and running. Some of you are
familiar with me, as a receiver designer, and have asked me to do this for a
long time. I've got all of the design information, including full size PDF
board layouts, schematics, DDS code, theory of operation, and parts
placement diagrams. The nice thing about the PDFs is that you can print
them out either on Inkjet or Laserjet transparencies, giving you a good tool
to use with photosensitized boards. I've also put up a few other things,
such as a high output RF noise source, a white noise source for audio use, a
general purpose SSB detector for use with boatanchor receivers, and a LW/MW
bandswitched active loopstick antenna. The url is:
http://home.att.net/~n.gianakopoulos/wsb/html/view.cgi-home.html-.html
I want to thank all of the folks on this NG that helped me fine tune things.
Folks like Kenneth Scharf, Phil (R75 guy), Dale Parfitt, Neil Heckt of
Almost All Digital Electronics, and many others.....you've
all made this possible.
Thanks folks!!!!!!!!!!!!!!!!!!!!

Pete

Dick, well, you could hardly disagree with yourself. ;o)

The system is PLANNED to provide the transmitter with a resistive load of 50 ohms and that's all the meter is required to indicate. And the meter should be named appropriately.

As there IS no reflected power, neither is there a transmission line on which an swr can be indicated, why bother to introduce misleading fictional quantities to novices?

That's how 'old wives' tales are initiated. ;o)

Cross-posted to: alt.ham-radio.mods,rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

Hi. The old FR50B is quite a nice Rx. However, this budget rx needs modifications to make some needed performance improvements. Just wondering if anyone has done a digital VFO mod. I could simply put in a pretty stable VFO (capacitor tuned) and add a digital frequency counter, but I'm really wanting zero drift and precise frequency readout, and I think only a digital VFO will give me that. VFO could also tune the Tx. So, if you have done all the design and put in a digital VFO, please let me know. :c) Later on I'll probably be asking about a filter mod. I have the RadCom mod articles by G3YUQ & A8346. I need the Rx circuit diagram. I wonder if it could be emailed me. Thanks. Rich.

Does it have to be positive resist? I know it is easier that way but
most CAD software will allow you to reverse the image. Reversing film
is also an option although not an ideal one. That being said, I have
not found a good source for negative resist. Datak sells some but it
is in a pump bottle and requires a 20 minute exposure time under two
18" black lights.

We have a clown here in the UK that would give Bush a run for his
money in this respect: Bliar's deputy, John Prescott. I've seen a
compilation of some of his TV pronouncements (misquotes therefore not
possible) and it's truly jaw-dropping stuff.

The problem is not the CAD package, it's the laser printer. My printer tends to "bleed" to fatter lines. If I use positive lines they'll be a little fatter, but that's OK. If I use negative lines the black bleeds to make the lines very skinny.

> Reversing film
> is also an option although not an ideal one. That being said, I have

I used to have that problem with Kodak's KPR photoresist, and what was happening was that the solvent in the resist was not fully evaporating before exposure, sometimes even after waiting over night. I found that waiting several days helped, as did baking the coated board at about 120 degrees (*loooow* heat, else the resist burns) for half an hour or so. I have no idea what formulation Datak uses, so this trick may or may not work.

Well...last I checked, AZ111 was still available, though not from
Shipley. (If I'm not mistaken, Shipley was making it under license,
or perhaps even just re-selling it; I think the patents are/were
owned by Azoplate.) The problem was that it was available only in
something like a 4 or 5 liter put-up, at a bit over $1000. There was
a time when I was using enough of it that I might have gone for that
much, but now it would last me a bit too long. OTOH, if we could get
together a large enough group... But are there, say, 20 or 30 of us
out here who are serious enough about it to buy some and split an
order? And...is there perhaps a better resist available now? I mean,
AZ111 isn't nearly as sensitive as what's coated on pre-coated boards
I buy. Also, the sales guy I talked with didn't seem very willing to
help me find a different resist that would work better, but there was
an indication that some of the others could be bought in smaller
quantities. Also, I had an email exchange with a fellow who was
looking into re-selling small quantities of a different Azoplate
positive resist; he was in the Vancouver, BC, area. I think he
decided that was too much trouble, especially shipping across the
border.

I've also considered buying some negative laminating film; you can
also get photo solder mask laminating film, and it would be nice to be
able to do solder masks. But the investment in laminating equipment
has put me off so far. I don't know if the relatively inexpensive
laminating machines available in office supply stores will work, or if
you have to go with a fancier (and much more expensive) machine to get

decent results. Someone suggested to me that it might even work to iron it on, if you had an iron that would hold a constant enough temperature.

Cheers,
Tom

>
Is this a bit garbled, or have I missed something? In the May 1961
issue of QST, there is an article entitled "Balanced Detector in a TRF
Receiver". I have it, but I can't find it at the moment. It had
a stage of amplification, a balanced mixer using something like a pentode
(the 6SB7 sound about right), and it was in effect a "direct conversion"
receiver. But it didn't use phasing, so there was an audio image.

(There were of course plenty of adaptors that used phasing to get
rid of the audio image, and they could have been used this way, but
I've never come across something in the tube age, ether directly or
by reference.)

One could argue that this is the origin of modern "direct conversion",
though the article does not use that term.

Realistically, it is just a variation on a regen receiver with regen
set into oscillation. And as you, and others, have pointed out elsewhere
in this thread, there were early attempts at using such a scheme for
reception early on, and I've seen enough variation (and haven't seen

original texts) to be unable to keep track of the various names for the same basic concept.

That 1961 article seemed an attempt at reviving the concept, and isn't really a surprise with all the talk of product detectors in the magazines and hobby in the previous 15 years or so.

The origin of the term "direct conversion" seems to be "Direct Conversion -- A Neglected Technique" by Hayward and Bingham, in QST for November 1968. It uses four hot carrier diodes in a double balanced ring mixer. I believe it references the 1961 article. This did set things afire, since after that most simple receivers for a number of years were direct conversion, until there was a turn back to simple superheterodyne receivers, fueled by the interest in crystal ladder filters. Obviously the technique did not originate with transistors, though they seemed the impetus for people to play with them in recent decades, but I do not think the term was applied until after this article.

The September 1969 issue of QST had "A Direct Conversion SSB Receiver" by Richard S. Taylor. It extended the Hayward article by adding a second mixer and a B&W phase shift network, so the unwanted sideband was knocked out considerably. (There was an article in Ham Radio magazine around the same time, for a simple CW transceiver with a phasing direct conversion receiver, but I don't know if it predates this QST article.)

After the Hayward article, of course there were various attempts at making the scheme better, though all the effort went into different types of mixers. I don't think there was a major forward step until Roy Lewallen terminated the ring mixer (which admittedly had been done with mixers going to an IF) in his "Optimized QRP Transceiver" in QST for August 1980. That set the stage for Paul Breed's direct conversion phasing receiver in QST for January 1988, and Rick Campbell's various high performance direct conversion receivers in the 1990's.

Of course, the scheme is fairly common now in commercial circuits, where the scheme is used to get the signal down where an A/D converter can work for digital processing. I believe "Zero IF" is the term used in such circles.

You need a high impedance speaker because it is a high impedance circuit and a low impedance speaker will need more than the circuit has got to drive it. A crystal earpiece works well, also a LM386 amplifier works very well to bring the level up to drive a standard 8 ohm speaker

One type of resist that I have used is a blue film that you print on
with a photo copy
machine or a laser printer (positive) and then iron on to the circuit
board. You need
to use a good hot iron and clean and pre heat the copper board first.
Then when it
cools you peel off the sheet and it leaves the resist behind. It worked
good for
simple single sided boards, with care to maintain registration you might
be able
to do double sided with this. Of course you can't make vias (plated
through holes).
I forget who made this stuff, but the blue clad film was the best type.

==========
I usually purchase scrap double sided fibre glass PCB by the kilogramme at
Continental European amateur radio fleamarkets .
Various sizes up to 2 by 2 feet. Excellent for making project enclosures
as well.
2 large well known flea markets in PA-land where these cut-offs are normally
available are the one at Rosmalen (Autotron site) near 's Hertogenbosch
,this year to be held on 8 March and on the last Saturday of September at
Trucker's Parking lot 'Lichtmis' north of Zwolle . There should be others in
Germany, one being the rally at Friedichshafen (Bodensee) near the border
with Switzerland , in June each year.

Absolutely not. The book is excellent. It's just
the whiners who will always find something to bitch
about.

"Direct conversion" is so well established a term
(since at least 1968 - "Direct Conversion - a neglected
technique", Hayward and Bingham, QST, November 1968)
that anybody who would question the term is either
a troll or has been asleep for the past 35 years.
Of course, this *is* a ham radio newsgroup, so this
is far from a rhetorical question...

The image-reject receiver others mentioned may be
"A Direct-Conversion SSB Receiver" by Richard Taylor
W1DAX, QST, September 1969. I have it in front of me
as reprinted in Single Sideband for the Radio Amateur,
5th edition, 1970 (picked up at a flea market last
weekend). It uses a 2Q4 phase shift network in a
solid state image-reject direct conversion receiver.

There was something by G3WZT in RadCom a few years back, as part of the
description of his solid-state 600W 6m amp. Sorry, I don't have the
exact reference to hand.

I'm kinda being lazy at the moment asking this without doing research, but anyone know, off top of head, what kind of frequency stability I could expect from a non digital VFO. I mean a VFO capacitor tuned and using some kind of PLL /"huff and puff" circuit to maintain frequency? Maybe I don't need to build a digital VFO, and I can stick with the variable capacitor in my FR50B . I wonder if I could acheive xtal osc frequency stability. TIA. Rich.

I have built 3 huff-and-puff VFO stabilizers for frequencies from 6 MHz up to 12 MHz. All seem to work adequately, even with PSK31 which is rather sensitive for frequency drift.

You should remember that the frequency can be adjusted only with steps, in my case 10 Hz is the smallest step I have tried. When properly settled, the frequency is constant within a few herz. Manual tuning with capacitor or varicap is OK, after adjustment it takes 1-2 s to reach the stabile frequency spot. You should not try to modulate the oscillator (FSK, FM) because this will ruin the operation of the stabilizer

In my opinion, this kind of device with a free-running VFO is a good substitute for a PLL with similar frequency resolution. One drawback is the number of parts required when compared with the oscillator as such. Also, the tuning sensitivity of the varicap needed seems to be a little bit critical. Values (1 kHz/V) suggested in the references should be used, otherwise the frequency may start jumping between two points as was the case in my first project. hihi.

Thank you Laura,

I cannot believe the number of people condescending to others because of their own ignorance on the subject. This group is usually much better than this.

I hope someone has been able to help Bert out. The only direct conversion I built so far is the MRX-80. The lack of selectivity was great coupled to a waterfall display. I saw 8 or more CW QSO's with a PSK signal, very cool.

Regards,

Christopher Cox

I guess if if I can use a variable capacitor to tune, (As oppossed to using varicap diodes) and get excellent frequency stability I ought to keep the Rx tuning capacitor. Well, that's a thought.

Is PLL different from "huff-and-puff" or are they the same technique?

(Again being somewhat lazy just at this moment).

Rich.

1650. Custom Transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-05 15:13:22 UTC
From: Hans Summers <Hans.Summers@Tudor.Com>
Message-ID: <b4546j$1r63lc$1@ID-61331.news.dfncis.de>
Source record: 37253

I have located a UK company Airlink http://www.airlinktransformers.com/ able to wind me a custom transformer for the PSU of my all-valve 80m/20m CW/SSB tranceiver project, at what I consider to be a reasonable price, given that a transformer the size I am looking for seems to be impossible to find otherwise, new or old. The cost is substantially less in QTY 10+ so am looking for other interested parties.

These are high quality 225VA toroidal transformers with 20cm flying leads supplied with mounting hardware. The secondaries are:

2x 250V @ 250mA (for series 250-0-250 or parallel connection)
6.3V @ 10A (filament supply)
5V @ 3A (suit GZ33, GZ34 etc. rectifier filament).

Prices are:

1+ ?36.25 (US $58)
10+ ?17.21 (US $28)
25+ ?15.40 (US $25)

Postage is ?8 per box of 8 to me here in the UK. Onward shipping would be ?6.95 to UK destinations but likely to be substantially more overseas.

Anyone interested?

Hi Hans.

This was the post that I put out down below "Circuit from new ARRL RF Design Book" and I was hoping to find others who were dabbling with circuits in it (but the thread became an argument about what direct conversion was!).

Have you built any of the circuits in it yet, and if so which ones? I like the book too, but it is definitely not for beginners, as in the first chapter they dive right into several circuits without a whole lot of explanation. I do like the fact that there are a lot of schematics in it though, as I can research the circuits out on my own if need be. At least I have the diagrams as a starting point.

73,
Bert

With most computers, the bulk of the RF leakage is from cables entering and
leaving the cabinet, if the cabinet is properly grounded.

To be fair, the book has only been out a few weeks. It's also
fairly expensive as a hobby book, more than the ARRL Handbook. I assume I
will get it, but at something like $75 Canadian, it's easy to put off
the purchase.

You might have been better off describing the circuit, rather than
hoping to find someone who already has the book. It sounds like
the specific circuit is fairly generic, and you might get more help
at that level.

A lot of material in ARRL books is plundered from QST articles. I
get the impression that this book, like "Solid State Design for the Radio
Amateur", is more original than many of the others, but still the
circuits may have come from elsewhere.

As someone mentioned, it isn't aimed specifically at beginners. One reason
"Solid State..." is still an appealing book a quarter century after it
came out is that it dealt with topics that weren't covered well in
the Handbook. You're probably expected to have other books on hand.

Some cases are pretty bad at this, as they have extra holes and
openings, or gaps where panels meet. You might need to add a little
bit more metal in these places (experiment with foil).

Also, make sure you use high end cables with shielding.

Monitors, CRT or LCD, can also be a source of RF.

Happy trails,
Gary (net.yogi.bear)

I'm seeking a 5.2 Mhz crystal filter with bandwith about 2.5 or 3Khz, or in between. Article mentions suitable commercial filters being QC1246AA or QC1246AC (made by SEI?). Do you have something in your junkbox? Ta. Rich.

Hi Guys,

I decided that the Hex-Beam would be a good bet for the foreseable future.
I currently own an IC-735.

The question is what are the pros and cons of bamboo and fiberglass spreaders?
I figure that I could get the bamboo spreaders at NO cost, but they will eventually rotten and break.
Fiberglass material is expensive, but the way I see it may last many years.
Then one issue arises... Would it be better to use telescoping sections of FG tubes or a solid rod would be better?

Next week I have an appointment with the FG salesman, so I may have some answers (will post on the NGs r.r.a.a and r.r.a.h)

Almost forgot to mention... I live in SE Brazil (sunny, rainy), with a possible move to NE Brazil (really sunny, quite dry) in the next months

From: Jan Wagner <jwagner@cc.hut.fi>
Message-ID: <b45il7$2mc$2@nyytiset.pp.htv.fi>
Source record: 37264

Hi,

I'd like to write a soundcard driver which uses an existing soundcard for recording, and then demodulate the audio (== I/Q demodulation done in software :-), and present it to other OS apps via a virtual sound card so the apps can "record" from that virtual card.

Is any bare-bones source code for a software based soundcards available anywhere? Or has someone already written something like this?

Thanks!

cheers,
- jfw

So, if you are allowed to be somewhat lazy, can I also be? :-) I'm
not sure what you mean by "huff-and-puff", but for sure, a
frequency-locked-loop (what I suspect you mean by h-a-p) is not the
same as a phase locked loop. And not all PLLs are created equal, for
sure. If you run the phase comparator of the PLL at a very low
frequency so you get very close spacing of available frequencies, then
the PLL won't be able to take out phase noise at even moderate offsets
from the carrier. There are lots of tricks to get away from that
problem. I believe the "fractional-n" PLL as originally patented by
HP (C.K-S) does, for example, but it's a bit complex to implement
properly. There are several variations on the theme of multiple-loop
PLLs, too; for example, if you have something that can take 10kHz
steps, and something that can take 9.99kHz steps, the sum (or
difference) can take 10Hz steps and benefit from the much wider loop
bandwidth. But again, the complexity is likely beyond what you want.

So...to keep things simple but good performance, make a VFO oscillator
with inherently good phase noise, give it voltage control that can
take out whatever long-term drift you anticipate (that is, a very
limited voltage control range), and control it with a very simple PLL
running from a decent crystal source. Although a PLL takes a bit more
logic (more divider stages) than an FLL, it shouldn't be hard to fit
one into a single medium-size CPLD, or perhaps a small microcontroller
with a tiny bit of external logic.

Cheers,
Tom

Gary, the book is published by the ARRL, so therefore to certain folks
this means it must be inferior.

I bought the thing the day it came out. It's nothing short of
fantastic. I feel it was a well spent $49.95. You can spend a month
on chapter one just having fun building the little circuits there.

I recommend it.

If you know the core material, you can download the datasheet. There you can find the core losses in mW/cm^3 or W/cm^3, vs the frequency and flux density. With that info, you can estimate the total power loss and temperature rise. Winding losses come extra.

I think his question was- given the mW, how do you determine the
temperature rise of the core?

Ah, ok, maybe I misunderstood... Well anyways, after estimating the core power loss, you could use the specific heat to calculate the temperature rise over time. If you're lucky, the specific heat _could_ be given in the datasheet of the material. I just had a quick look at TDK PC40 material specs for high power cores, they specified 600 J/(kg*K) as the specific heat and 420kW/m^3 100kHz 200mT. Just an example. Abraham Pressman's "Switching power supply design" went into very detailed loss analysis, IIRC, though I don't have that book at hand right now and can't check...

OTOH, it might be simpler to just test a core and see if it gets way too hot during a long term run. Then add a huge fan if necessary... ;-)

cheers,
- jfw

I think I have the "Solid State Design" book -- is it the one with what looks like a bunch of dominos on the cover? Kind of a brown cover and paperback? If that's the one, then I didn't feel like it was all that much better. Frankly I'm not sure the kind of book I'm looking for exists, from what I've seen. I'm looking for something which goes through lengthy explanations on various oscillator circuits, including why values are chosen as they are, what is critical and what isn't, and some circuit analysis and simulations, where they talk about impedances and so forth. For me a book which spends more time examining the fundamentals like that would be better than having lots of complicated circuits thrown at me. If you don't have a solid grasp on the fundamentals, it is difficult to add layers of complexity.

>xtal osc frequency stability. TIA. Rich.

If you use a "huff&puff" method of stabilization, you will stabilize
between the end-points of the increments of the stabilizer. It will
remain accurate to that within the incremental range plus the
reference crystal oscillator stability.

If you were to just stablize an L-C VFO without anything else in the
way of a stabilizer, you could achieve 50 PPM (Parts Per Million)
with a lot of work, patience, a frequency counter accurate to
better than 10 PPM, and a sensitive temperature sensor. As a
very rough estimate, working two hours a night, three hours a
week, you might reach 50 PPM stability over a 20 degree C
ambient in about three months. [50 PPM is a common crystal
oscillator tolerance/stability for just the crystal unit]

For stability of any L-C VFO you must begin with stable power
supplies (including heater if a tube type), fairly easy to check
with a DMM accurate to 1% or better. Next, you need to plot the
VFO L-C part internal temperature versus ambient temperature,
assuming that ambient is something like 16 C to 33 C (60 F to
90 F roughly). Then you need to find out the temperature
coefficients of the L and C components...you might be able to
do that by examination of the fixed capacitor markings, mfg
part number v. their specifications. The inductance will
probably be indeterminate/unknown as to temp coefficient.

The next thing is to arm yourself with several values of NPO
and N750 fixed capacitors which you can use to replace some
of the existing fixed capacitors. From here on it's an iterative
process of step-and-repeat, substituting a known temp coef
part, measuring the frequency versus temperature change,
calculating the overall probable capacitance change (which

will include the inductance temp coef) and trying to spot a
trend in the change versus previous check to see which way
to go.

There's a saving grace in this iterative process. The percentage
change of either L or C will change the VFO frequency by the
negative square-root of that value. It isn't proportional so you have
some leeway. As a very approximate rule, but not absolutely true,
air-core inductors increase inductance (and lower the frequency)
with increasing temperature and most fixed capacitances will
decrease with increasing temperature (and raise the frequency).
The iterative process will eventually zero-in on on a compromise
of (probably) of mix of fixed capacitors, part of which are essentially
zero tempco (NPO characteristic) and negative 750 PPM per deg
C (N750 characteristic).

Note: If this is a VFO with less than 10% tuning change versus
mean center frequency, do all of the iterative tests somewhere
near mid-frequency-range. Lock the tuning control down to keep
from adding to measurement inaccuracy. Use a calculator to
relate fixed capacitor changes to measured frequency-over-
temperature values...changes are small so at least 8-digit
calculation is a necessity.

All of the above requires a major amount of hobby time so do one
thing first: Carefully measure the existing VFO frequency at a
fixed frequency using an accurate frequency counter with variations
first of line voltage, then ambient temperature. This is a good time
for that in the northern hemisphere. Some room will be cold to let
the unit reach some low temperature thermal equilibrium. A
couple of incandescent lights shining on the cabinet can hurry
the warm-up. If the existing frequency changes are within what
you want for stability, you need not go further.

Note: 50 PPM change at 10 MHz nominal equals 500 Hz change.
50 PPM is also equal to 0.005 percent.

1674. Re: motorola msr 2000 vhf manual wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-06 00:25:53 UTC
From: Skipp has things on the sonic server <notmyrealaddress@yahoo.com>
Message-ID: <b464ih$q4f$4@woodrow.ucdavis.edu>
Source record: 37278

Another Shameless Plug... with some information...

The Motorola MSR-2000 was made in more versions than one might imagine... both in base station and repeater layouts.

There are three basic manuals for the MSR-2000, however, only two are required for the VHF system.

The first manual is (similar to the micor line) based on the control chassis ("backplane") and the control modules. It has an orange'ish band across the white cover. Call it the control station manual...

The second manual has VHF transmitter, receiver, rf amplifier and power supply circuit. The vhf version had a green band on the white cover. Call it the VHF RF Manual

The third manual has UHF rf equipment, the duplexer and no power supply information, the white cover has the blue band. Call it the UHF RF Manual.

You can go to the http://sonic.ucdavis.edu edu web server where I have an article on using an MSR 2000 and or Micor with an external repeater controller through simple connections via the squelch gate card. Part of the package includes the proper manual part numbers.

You can then call Motorola parts and simply order them. Or... check Ebay and try to outbid the sharks.

You can Email me from the sonic server with MSR 2000 questions as I have many MSRs in trunking, paging, conventional repeater and base applications. Yes, you read the trunking part right...

I've worked up, but not yet posted on the sonic server, the entire conversion of an MSR to an external tone panel (and or trunking controller). I've done all the homework and the mod works very very well. Mentioned controllers are the CSI-TP163 and the Comm Spec TP-3200.

I'm an Authorized Kenwood Dealer, but I support all brands as possible.

****

The MSR 2000 and the mobile mitrek use the same channel elements. You can buy surplus elements cheap from CW Wolfe Communications in Billings Montana, ask bud and tell him skipp sent you for a great price.

****

Canadian MSR-2000 units had 30 watt rated power amplifiers... you will need the Canadian MSR Manual to service the PA deck... or you can work

with a Mitrek Mobile book and a similar circuit. I've never had a 30 watt PA fail, just mis adjustment of the power control board shutting things down.

There are various versions of VHF and UHF high power amplifiers... based on power level and duty cycle. 30 watt, 110 watt and 110 watt plus, high duty cycle (the micor style).

The standard MSR 110 watt PA has an honest 40% continous duty rating... constant use will burn it up.

The continous duty VHF power amplifier is the basic Micor Repeater PA painted black... you'd be hard pressed to kill it.

Big PA killers are heat and out of band high/full power operation causing damage in specific spots. If you want the PA to last, run it at least half power into the ham bands (unless you have the pa strip originally built for the amateur band range).

OK, hope that helps... contact me through the http://sonic.ucdavis.edu web server Email icons if you have a question. I'm probably up on the MSR more than anyone else and I work cheap... buy me a cup of Joe at Dayton for most answer.

cheers
skipp

>I think I have the "Solid State Design" book --

Yes, if it says "Solid State Design" across the top, you have it.

>Frankly I'm not sure the kind of book I'm looking for exists,

You are looking for what I have been for years. A book that makes complex subjects easy to understand. I have not found a single book, but have a small library that helps.

It seems to me you are looking for an "Instant Gratification" type book, which may not exsist. You have to dig thru the references that you do have, and if you conclude that they are not enough, then look for more. Still not satisfactory, enroll in a University that teaches the lengthy explanations that you require. I don't think a ham radio publication will help you.

>'m looking for something which goes through lengthy
>explanations on various oscillator circuits, including why values are chosen
>as they are, what is critical and what isn't, and some circuit analysis and
>simulations, where they talk about

Get a college textbook on electronics, a book on switching and transient circuits, a book on high frequency transistor models, rf circuit analysis ect. I don't think you will find a single book that will cover what you want.

>
> Don't forget that many radios shift frequency about 800 Hz when going from
> SSB to CW.
>
> Bill K7NOM
>

The bfo or carrier oscillator is placed about 200 to 400 hz outside the
band width of the
if filter. This gives an audio response of about 200-400 hz to the
filter BW+(200-400hz).
It also means you CAN'T hear the zero beat. It also gives single signal
reception on CW.
If the bfo were placed within the bw of the if filter you would hear the
zero beat, and a
little bit on the other side of zero beat. You would also not have full
reverse sideband
rejection.

Some rigs shift the carrier oscillator to offset the transmitter for cw
operation. Otherwise

one of the stations would have to retune when going from tx to rx.
Another way is to
inject a pure sine wave audio signal into the balanced modulator and key
that signal to
generate the cw carrier. This automaticly shifts the transmitter
frequency from the rx
without having to switch carrier frequencies. When shifting from LSB to
USB the LO must
shift to keep the rig tuned to the same frequency.

1677. looking for a HP 8568B spectrum analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-06 05:42:19 UTC
From: paulmcd101@hotmail.com
Message-ID: <f93f1dc3.0303052142.4245b99b@posting.google.com>
Source record: 37281

I'm looking for a HP 8568B spectrum analyzer for less
than $1500 that Ebay wants for it (and I can't stand the
way the price doubles in the last 60 seconds of an auction,
argh!).

I'm doing radio homebrewing, testing and measurement of received
HF signals to a frequency accuracy of about 10 Hz (no I don't
need the 1.5 GHz upper end of the 8568, but I need the
frequency accuracy and low noise floor at narrow BW -
that's why the HP 141T won't work).

Does anyone have one of these lying around, gathering dust,
that they'd like to part with to a budding radio engineer?
This is for personal/ham radio design use only.

I'm in Medford, Massachusetts, if that helps.

Thanks,
Paul

p.s. Yes, I already have a great dual trace Tek 7603 scope
and Tek freq counters and RF signal sources. But thanks
anyways! (Thanks, Dick! QSL?)

Try http://www.golledge.com/

They are friendly and helpful and will sell one offs. Quite cheap
too. 5.2 MHz is not a standard frequency crystal, nearest is 5.120000.

What sort of frequency band should we be searching? Something in the
back of my mind tells me IRO 5 or 6Mhz, but I may be way off here.
Anyone know?

Source record: 37287

Hi Group,

I have a Wavetek 3000-200 signal generator which is just like the 3000/3001 units but also has the FM deviation meter.

I am not sure how to use the deviation meter, would like to get some help. I don't believe that it is working at this time.

If anyone can scan the manual page with the information on how to use the feature and the schematic of the board for this part of the 3000-200 would be of great help.

Thanks,

Paul

1684. Re: Non digital VFO frequency stability

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-06 14:51:48 UTC
From: Richard Hosking <richardh@iinet.net.au>

Huff and puff is a form of PLL In the case of my VFO stabilizer at

http://members.iinet.net.au/~richardh/vfostab.htm

the micro counts the freq and then outputs positive or negative pulses (huff or puff) to keep the VFO at the same count. If the VFO changes between counts by more than a certain amount (say 30-50Hz) then the micro assumes it is being tuned and waits until it is stable again before lock. This has the effect of a software lock which is invisible to the user. You get a bonus frequency display as well! This module was based on the one by Eamon Skelton in Elektor a few years back.

Here's a link to the primary U.S. supplier of fiberglass tubing for
ham antennas.

http://www.mgs4u.com/fiberg.htm

You might find it useful for cost comparisons. Prices are in U.S.
Dollars, dimensionss are in inches/feet, weights are pounds.

...(Lots of detail deleted...)
> Len Anderson
> retired (from regular hours) electronic engineer person
I suppose that should be six hours a week, if it comes in two hours
per night increments, assuming three nights a week of work on it??

But of course, if one implemented a PLL instead, using a decent freq
ref, "one" could do it in just a few weeks of that hobby time, and
know up front that the long-term frequency stability would be the same
as the reference. Since 1ppm-over-temp references are easy to find
and not terribly expensive, that might be a decent goal*.
"Solid-State Design for the Radio Amateur" has a circuit for a
low-phase-noise LC oscillator that should do fine for the VCO, so
there's not much hobby time involved in that. And of course, if

there's an available reference design for the PLL part, that speeds things up a lot, too.

The way that the HP8640B implemented a PLL should work quite nicely for such a task: the essence is to count the frequency in a free-run mode, and when you want to lock the frequency, use the frequency count to set the "N" in a synchronous divide-by-N from the vco frequency, feeding a true phase comparator. In the early 1970's when the 8640 was designed, it took quite a few logic chips to do it, but now, doing it all in a CPLD (except for the PLL filter) should be no big deal. (Having done a couple CPLD PLLs in a slightly different context, I have a trick or two I could share if anyone is serious about trying this.)

Cheers,
Tom

* I have a few decent TCXO cans in my junque box. If there's someone in need of one for a project like this and can convince me they really are going to do it, they can have one for the postage.

Steve,

Not quite sure what you mean, "not a standalone book." The ARRL web site says it replaces "Solid-State Design for the Radio Amateur," which seems to no longer be offered, so I hope you're not meaning that one should have both. Newcomers may be out of luck!

Certainly no book is truly "standalone." All assume _some_ knowledge on the part of the reader, if not the ability to reference other specific books.

Cheers,
Tom

:-) I'll agree with you on that, Gary, and I'd add, "and get a nice
set of gurus to consult." I've had the good fortune to work with some
folk who are among the very best at low-noise RF oscillator design
and implementation, and picking their brains has gotten me things that
I'm quite sure aren't written in any normally available books. But
there's a lot of experience in the ham community, and if you can tap
into it, you can sure bootstrap your learning faster than just reading
one book. r.r.a.h. is one way to do it, though you have to learn how
to separate the wheat from the chaff.

Cheers,
Tom

> This is for personal/ham radio design use only.

Of course, it's not Ebay that wants the $1500, it's that the bidders
believe the equipment is worth it. If I had one "lying around
gathering dust," why would I sell it to you for significantly less
than what it would fetch on Ebay? So--there may indeed be a reason:
for example, because I thought you had talent that would be worth
contributing to, to develop. Do you really "need" one for your home
workbench? Or could you use one at, say, a nearby community college,
or on the bench of some Elmer? What if someone could loan or rent one
to you?

And...what upper frequency _do_ you want to cover? What frequency
accuracy do you need? What minimum resolution bandwidth? What
display capability? Could you do what you need with a general-purpose
non-synthesized wideband analyzer, combined with something that could
get you high-res narrow spans? (Do you already have a good
generator?) Are you willing to hack your own equipment? (There's a
lot to be learned in doing that, too!)

Cheers,
Tom

For sale:

For experimenting or what have you.. I have "approximately" 10 crystals for sale cheap.
I got them in a lot purchase. Not sure of their intended use.

They are marked as such:

side 1: 1.78K
.1%

side 2: Vishay
7035
HP202

Can you use these? $2 each. Buy all available and I'll pay the shipping.

E-mail directly please. Thanks.

1698. An AB2 amplifier modulated.

Newsgroup: rec.radio.amateur.homebrew

Hello folks,

I was wondering, what will happen if i modulate a grounded grid AB2
amplifier with an external modulator for highpower AM.
normely class c will be used, but then the amp has to be rebuild (don't want to do that).

The amp. uses pentode tubes (EL509),so the question is can I get a modulation depth of 90
... 100%.
With this amplifier, without a lot of disortion.

I surft the net, with no results for any information, it seems nobody doesn't do it this
way. why??

So any Ideas, or better, Good information ????

WFG Mojito

Just want to say that a good place to look for glasfiber
roods is compagnys that is making fishing poles,
kites and ultra light aeroplanes.

Regards Max

Mojito:

To quote Bill Orr, W6SAI: "Plate modulation is the application of the audio power to the plate circuit of an r-f amplifier. The r-f amplifier must be operated class C for this type of modulation in order to obtain a radio-frequency output which changes in exact accord with the variation in plate voltage."

If you plate modulate a class AB2 mode amp, you will get distorted output. And adding class C capability shouldn't require a "rebuild" of the amp. You didn't say whether it is grid driven or cathode driven (grounded grid) but it may be possible to put it into class C with a zener diode in the cathode circuit. If grounded grid, keep in mind that much of the drive power appears in the output and unless it is also modulated, you will never achieve 100% modulation.

Mojito:

I just re-read your post and you did say it was grounded grid. How is it biased now? Is it biased with a separate DC supply or with with some voltage dropping component in the cathode? Or perhaps zero bias (don't know if those tubes can be run that way). You will need to examine the circuit to see how to change it to class C. It may not be too hard to make it class C, but that still leaves the issue of feed through power.

Roger

I believe you simple go 2 mhz above or below the signal frequency.

Pete
